Sclerotic, the outer layer or coat of the eye, dense and fibrous, stretched over the vascular choroid tissue, or infundibulum, or iris, and, when diseased, is always marked by livid congestion and severe aching round the eyeball; and rheumatism is frequently the cause of trouble in the sclerotic coat. Sclerophthalmia

is the technical term for a painfully swollen and hard condition of the eyes and eyeball, incident to the part of the visual organ here mentioned.

Scribner's Palsy or "**Writer's Cramp**," A species of local paralysis of the muscles of the hand and fingers induced by their overwork. (See *Paralysis*.)

Scrofula, indicates lowered constitutional vitality, which may tend to produce many forms of distressing disease, first of a glandular character, and later more extensive and serious. If it is not to culminate in consumption it should be coped with immediately upon manifestation. Muriate of calcium is a splendid specific, cod-liver oil and extract of malt are most invaluable remedial agents, systematically employed from the beginning. If the scrofulous tendency is not conquered by the restoration of healthful energy there will certainly be suppuration in the absorbent glands, and should this not be properly treated by the evacuation of pus, ugly scars will result.

Scurf arises from unhealthy condition of the skin of the scalp due to the circumstance that the cells which cover the outer cuticular layer are prevented from living at maturity, and are consequently thrown off in the form of dandruff (which see). A simple application for this ailment is an admixture of the best vinegar with water in which a lump of quick-lime has been dissolved overnight, the liquid being strained from sediment. The roots of the hair only need to be wetted, and the application is quite harmless.

Scurvy, a disease due to want of sufficient potash in the food, is characterised by livid spots, debility and constitutional exhaustion, and often attended by febrile breath and bleeding from the mucous membranes. Belongs to the large class of preventable maladies which increasing observance of the laws of health and dietary have within living memory very much reduced in extent and frequency. Where scurvy occurs at all its treatment usually consists in the administration of plentiful supplies of lime or lemon juice, containing substances allied to potash, to make up for the lack of vegetable essences in the food which brought about the mischief.

Sorbals are hardened feces from which the liquids have been absorbed during undue retention in the bowels. So long as they are permitted to remain they will occasion more or less obstruction and irritation, and may induce febrile conditions—and in children give rise to convulsions. Hence it is always advisable to effect their removal by the use of an enema, or irruptions of soap and tepid water.

Sebaceous Glands. The sebaceous glands are those minute fatty glands of the skin which secrete a oily matter for moistening and rendering it elastic. They are clogged at the outer extremity, their pores being dirt get "blackheads" or acne. Cleanliness and frequent friction will keep the sebaceous glands in good tune. If they get out of order, extra attention with the use of a lotion composed of elder water, glycerine, rectified spirits, and flowers of sulphur will usually be found remedial.

Secretion signifies the powers possessed by the several organs of separating substances from the blood. Thus we have the secretions of bile by the liver, of the gastric juice by the stomach, and saliva by the salivary glands.

Sedatives are medicines designated to restrain the action of the various functions of the body, removing simultaneously sensibility to pain. Acting first upon the nervous system, they influence the secretions, and if properly selected and applied produce the results desired. Amongst the sedatives most commonly employed in medicine, all of which are referred to elsewhere, are chloroform, menthol, opium, belladonna, and bromide of potash and of sodium. All these and others act locally on external application, while administered internally they aid the system generally.

Senna, one of the most useful purgatives in the Pharmacopoeia, has been known as such in Arabia and the Orient for ages. A most effective article of domestic medicine, it should never be administered where there is inflammation or great irritation of the bowels, but as a palliative to habitual constipation it may be employed frequently without aggravation of the causes of the mischief.

Serous Membranes envelop the brain, line the chest and abdomen, and cover all the vital organs therein situated. Surrounding the brain the serous membrane is called *tachnoid*, in the abdomen the peritoneum, and in the chest the pleura, all of which secrete. White in health, it becomes red when inflamed, its vessels being charged with blood unduly, and is apt to form when thus disordered dangerous adhesions. Dropsies are occasioned by abnormal excretion from the serous membrane, through the blood fluid or serum collecting in cavities and not being carried away.

Serum, the fluid part of the blood. In a blister, scald, or burn, it collects under the skin, and exudes upon the puncture of the cuticle. Technically termed the liquor sanguinis and plasma, it largely consists of water, and holds in suspension the red and white blood corpuscles, and contains in solution salts of potash, soda, lime, and iron.

Shingles, the "herpes zona" or "zoster" of the scientists, is a peculiar and very troublesome disease of the skin, eruptive and inflammatory, generally attacking the trunk, and preceded by febrile conditions. Accompanied by scalding heat and tingling sensations, the shingles usually appear in early puberty when there is a debilitated constitutional condition, the eruptions spreading in a line from the front to the spine, filling with serum and breaking about the fourth day, leaving a dark scab which, on falling away, occasions slight pitting. Pain in the part sometimes follows, which may be relieved by anodyne application. Shingles indicate the necessity for general tonic treatment and generous dietary. (See *Herpes*.)

Short Sight, so called, arises from malformation in the cornea, and may be congenital or acquired by close occupation involving continuous eye-strain. Suitable glasses must be worn for the relief of the ailment, and rest may also be requisite. (See *Myopia*.)

Side Pain. A pain in the side may arise from some very unimportant cause, or it may point to the existence of serious mischief. If intensified upon drawing a long breath, it may very likely indicate an inflammatory condition of the pleura. If on the right side and low down, it is frequently associated with bowel trouble and appendicitis or with typhoid fever. Pain in the region of the groin in females often originates in ovarian disorder. Neuralgic spasms in the side commonly relate to some muscular rheumatic affection. In any case of continued side pain, the cause should be sought out and similarly treated.

Sinapism. A technical term for the mustard plaster or poultice.

Skin. The health of the individual is dependent very largely upon the proper performance of the skin's functions. Roughly, the skin may be divided into two portions—the dermis, or true skin, called also the cutis vera or corium, and the outer skin or epidermis, sometimes styled the cuticle or scarf-skin. The skin is continuous with the mucous membrane lining the passages to the interior of the body, and the mucous membrane. In the epithelial cells under the surface of the cuticle is carried the pigmentary matter which makes a man white, yellow, or black, and the epidermis varies in thickness according to the uses of the parts it covers. The dermis is made up of connective tissues enclosing the blood-vessels, nerves, and glands, and is extremely sensitive, requiring the wrapping of the elastic sensationless epithelial longer for its protection. The outer skin must have its pores kept constantly free from the exudations of the sweat glands by systematic lavation, combined with the requisite friction. This universal necessity of humankind can only be efficiently accomplished by the employment regularly and systematically of pure detergent soaps, such as Pears', the scientific preparation of which has been brought to perfection by the projectors of this Dictionary during a manufacturing career of nearly a century and a quarter's duration. (See also *Epidermis*.)

Skull. The cavity of the skull contains within its surrounding bony walls the brain structure. The cranium is formed of 22 separate bones inclusive of those of the face, united by sutures somewhat like saw-teeth. Each of these bones is made up of two tablets joined by a spongy central portion, the outer

plate being tough and fibrous, the inner hard and glassy. The porous middle layer of the skull bones serves to neutralise the effect of shock from falls or blows; and the division of the cranium into parts circumscribes fracture. The bones most liable to be accidentally broken are the frontal and parietal, or the forehead bone and those side ones which form in the skull cap the dome and walls of the cranium above the temples. A simple fracture under careful treatment will in repose unite and heal of itself; a compound fracture, accompanied by depression of an injured fragment and severe scalp laceration, is a grave matter, whether occasioning direct brain mischief or not, and calls for urgent surgical interference.

Slough. That portion of dead tissue to be separated from a wound, the result of inflammation or injury. The removal of a slough should be effected antiseptically always, for obvious reasons.

Small Intestine. (See *Duodenum, Ileum, and Jejunum*.)

Small Pox is rightly reckoned one of the most serious of all the eruptive diseases, though the ravages of the malady have been immensely reduced since sanitation obtained general and authoritative recognition. How much Jenner's discovery of vaccination and its compulsory application over a long series of years has had to do with this diminution in small pox cases it would be difficult to say, but the enforcement of hygienic observation, and the continuous vigilance exerted by the State in stamping out contagion have together contributed to the decline of small pox in a manner most wonderful. Small pox begins with shivering lassitude, "sinking at the stomach," intense headache and pain in the back, accompanied by fever and thirst. With the appearance of minute red spots on the forehead, neck, arms, wrists, chest and abdomen, and subsequently on the legs, commencing upon the third day, relief of the febrile symptoms is experienced. The eruption rapidly becomes more pronounced, the spots attaining the character of vesicles and running sometimes into each other, when we have the condition of confluent small pox. The pustules are each depressed at the summit, and about the sixth or seventh day after reaching maturity their contents have changed from serum into purulent matter. On the eighth day after the "spots" come out, the disease is at maturity, decomposition having occurred in the vesicles; and then very often comes on a secondary fever, an aggravation of that which preceded the eruption. This is the most usual fatal stage of the malady; but it can be obviated in many cases by the application of a solution of carbolic acid in glycerine to every pustule. Sometimes the swelling of the skin in the more malignant type of small pox is indescribably horrible. Little can be done beyond careful nursing during the course of the disease with disinfectant dressing, keeping the bowels regular, and supplying nutritive and digestive diet. Great care is requisite during convalescence. Isolation is essential, and the hospital patient makes the most speedy recovery.

Snake Bite, or at any rate, bite from the fangs of a poisonous reptile, in this country can only arise from the bite of the viper or adder. Wherever it occurs it calls for instant treatment. It may be necessary at once to excise the injured part surgically, so swift and deadly is the action of some snake poisons. A powerful alkali should at once be introduced into the wound, or it should be burnt with a red hot wire, and strong stimulants, such as alcohol or ammonia, administered internally. The sub-cutaneous injection of strychnine has the effect of counteracting the virus of the bite in a marvellous manner; this of course requires the watchful superintendence of a competent practitioner. Potassium permanganate of potash crystals moistened and rubbed into the bite, enlarged by cutting it, is a safe and satisfactory mode of treatment.

Snuffles is an indication of catarrhal irritation, and the sufferer should be kept for the time being in an apartment at an equable temperature, introducing into the nostrils a little vaseline, or permitting the inhalation of some such soothing vapour, as that arising from oil of eucalyptus.

Soap used upon the human skin should be made with such knowledge and of such material as to be

beneficial and in no wise injurious. Soap of this intrinsic worth is procurable only by buying the best, and eschewing all such as is made from inferior material or which contains irritant alkali in excess, no matter how showily made up or how meretriciously scented. The animal or vegetable fat employed ought to be of pure quality, combined with just enough soda or some other suitable alkali to neutralise the oleic acid and form the fats into an emulsion soluble in water. That is the principle of sound soap, the making of which requires carrying out with chemical and commercial integrity, and adapting to varied toilet requirements by the exercise of expert knowledge. Such soap will be found the world over stamped with the name of Pears. This soap has been manufactured for over a hundred and twenty years, and has always ranked as the highest attainable value in this important class of article. There are certain soaps which, medically, are much employed in pill preparation, to carry purgatives and other remedial substances; indeed, a pure soap pill would in itself possess slightly laxative properties. Soap always makes a convenient enema for injection in cases of constipation, and here again the spurious article should be avoided.

Sodium is a solid ready prepared by the chemists, and is very useful in chronic neuralgia and rheumatism, and is a vehicle for more active rubefacients. It is better known under the familiar name of opodeldoc.

Soda, an alkali extensively used in medicine in its bi-carbonate form, and especially serviceable in acid dyspepsia. Its over-free use is prejudicial, because of its directly stimulating effect upon the gastric glands. In combination with tartaric acid the bi-carbonate of soda makes a very good effervescent beverage.

Somnambulism, otherwise sleep-walking, is the term applied to the peculiar condition of nervous disturbance which includes all the unconscious actions occurring during sleep. It belongs to disturbed dreaming and pronounced nightmare, and is excited by disordered nerves, often so rendered by some irritant agency, such as indigestion, or its consequence, constipation. If the bodily functions are in orderly activity, abnormal and dangerous manifestations like walking, talking or screaming during sleep will be of rare occurrence.

Sore Throat may be a simple relaxation, a malignant ulceration, or anything in between. It is at times a premonitory symptom of some more or less serious ailment, as in scarlet fever, quinsy, diphtheria, etc., and as such is frequently diluted to under other headings in this Dictionary. A common accompaniment of cold and catarrh, it is generally benefited by inhalations of steam, medicated or otherwise, by the application of linseed or bran poultices, by keeping in a warm room for a day and by a Dover's powder at bedtime, followed by a mild aperient in the morning.

Speculum, an instrument employed by physicians in the diagnosis of internal disease.

Spine. The spinal column in the human adult consists of thirty-three bones, but certain bones are blended together. Such are the five forming the sacrum and the four forming the coccyx or "tail." The average length of the column is twenty-eight inches, the variation in stature of grown folk being chiefly dependent upon difference in the length of the lower limbs. The natural curves of the spine are sometimes exaggerated by disease, producing the deformity known as hump-back. It acts as the shield for the vital spinal marrow, as well as enabling us to maintain uprightness.

Spitting of Blood is usually indicative of the existence of stomach, lung, or throat disease, and therefore regarded with very justifiable gravity. A person so affected should observe as much quietude as possible, suck ice, and take some safe astringent solution pending the procurement of medical advice. The dietary should also be regulated so as to avoid irritation.

Spleen. An elongated gland, of soft and pulpy consistence, situated to the left of the stomach towards the diaphragm, this gland is believed to be concerned in the production of colour, and colouring blood globules and also assists in disposing of worn

out blood corpuscles. It is a soft, spongy body, purple in colour, connected to the left kidney by cellular membranes. A similar gland in animals is called the *melt*, and has from them been removed without apparent interference with the functions of any other organ. Well supplied with blood vessels, the spleen possesses no excretory duct or outlet, though it is four inches long, three inches wide and two inches thick. In protracted ague, particularly if much quinine has been taken, the spleen will often greatly enlarge.

Splint. A long piece of wood, gutta-percha, or even a walking-stick, umbrella, or sword, or other suitable substance, used to sustain a fractured bone in position during setting.

Spongopline. A mixture of desiccated sponge with cotton or other lint, and after being rendered antiseptic covered with waterproof material in the dressing of wounds, or used as a compress or in connection with fomentation.

Sputum. Expectoration. In lung disease this should be promptly destroyed or effectually disinfected.

Squill. The bulbous scilla, largely used in medicine as an expectorant and diuretic in dropsy, bronchitis, and catarrhal affections of the chest. It is administered as a syrup, ointment, or in the form of oxymel; also in combination with other remedial agents. It is a powerful drug and needs discreet administration.

Staphyloma, enlargement of the eyeball, with protuberance of the cornea, and consequent dim sight.

Steel is a splendid tonic, usually administered in form of tincture of iron or steel drops. The oxide of iron is the essential principal of the numerous steel preparations so much employed in the treatment of anemia. These preparations are mainly astringent, and readily absorbed.

Stings of Insects. Apply salt water, iodine, olive or unseed oil, or weak ammonia. If the sting be left in the wound, endeavour to extract same by pressing firmly over the puncture with a key barrel, or by using a small pair of forceps or tweezers. A hot poultice over the wound will often draw out the irritating object, affording immediate relief to the inflammation. Stings upon the tongue from a wasp in fruit eating are very dangerous, and should be treated at once by a doctor, as dangerous swelling, leading to suffocation, may ensue.

Stomach, the reservoir of our food and drink, the organ in which certain processes of digestion are carried out. Its principal office is the conversion of alimentary substances into chyme, a subject which has been sufficiently referred to elsewhere. The stomach is the seat of many ailments which affect the system generally in greater or less degree, and have had reference in their proper places. As the great Dr. Kitchener once well said, "The stomach is the centre of sympathy," and is disturbed by hurt occasioned to any fibre of the frame. It is never called upon to suffer without communicating pain to other organs in some manner; thus dyspepsia is immediately indicated by fretting headache, which vanishes upon the removal of its exciting cause.

Stone is a common term for the concretions caused in certain diseased conditions of the bladder and kidneys. (See *Gravel*, etc.)

Straining and difficulty of evacuation indicate an irritable condition of the colon, attributable chiefly to constipation or dysentery.

Stramonium, a common wild herb yielding a dry alleviative of asthma, for which the leaves are smoked in tobacco fashion; the seeds are sometimes employed medicinally in the treatment of rheumatism, asthma, sciatica, neuralgia, and tic. It is a substance, the use of which may make more mischief than it can correct, and so should not be used unless prescribed.

Strangury is a symptom of irritability and inflammation in the bladder, characterised by intense pain and difficulty in urination, and occasioning the passing of blood with the water.

Strangulation. A form of asphyxia, or suffocation by constriction of the throat, sometimes called throttling or garotting. Such strangulation cannot long continue without producing fatality.

Stricture, occurring in any of the bodily passages, may be temporary or permanent, and is in the first

case generally due to muscular spasm. This stricture of the urethra, or passage from the bladder, coming on often with suddenness, will give rise to straining after urination with inability for its accomplishment. The warm bath or an opiate may yield relief, but frequently the use of a catheter will be requisite. Permanent stricture is morbid contraction of the passage concerned mainly accounted for by cancer or humoral growth. Sometimes curable by surgery. Sometimes intractable to treatment.

Strychnine, a peculiarly poisonous alkaloid, obtained from the bean of *Nux Vomica*. In some forms of paralysis it is useful as an injection in small quantities, and is also antidotal to most snake poisons.

Stye, a painful pimple upon one of the eyelids, proceeding usually to suppuration and usually giving rise to considerable disturbance as well as pain. It is a kind of small boil in a most inconvenient situation, and indicates almost always a low condition of the general health. Hot fomentation, great care being exercised not to injure the eye, will usually afford relief by bringing the suppuration to a head, but the juncture may prove necessary. An aperient may help matters, with tonic treatment to follow. The eye should never be poulticed.

Sulphates, combinations of sulphuric acid—an oily liquid formed of three equivalents, one of oxygen and one of sulphur, with some metallic base, as sulphate of magnesia, sulphate of soda, etc. These salts are much used in medicine. Sulphate of zinc furnishes a very valuable astringent lotion.

Sulphur, an elementary inflammable body found in great quantities in volcanic neighbourhoods. It is employed medicinally as milk of sulphur, flowers of sulphur, confection of sulphur, and sulphur ointment. Its use internally will occasion the passing off of sulphuretted hydrogen from the skin, which will blacken any silver article carried upon the person. Sulphur (commonly called brimstone) in any of its forms exerts a laxative influence upon the bowels, and has also a purifying action. One to two teaspoonfuls may be taken by an adult before retiring.

Sulphuric Acid, or Oil of Vitriol, is used medicinally in a very dilute form as a tonic ingredient. It is largely employed in arts and manufacturing processes, and sometimes is the cause of caustic poisoning, most difficult to cope with. Alkaline substances immediately administered, such as chalk, magnesia, soda, potash, soap, or lime will convert the acid into a sulphate and rob it of its deadly effect. This accomplished and the drinking of such milk or oil as possible thereafter may save life, but not a moment must be lost.

Sulphuric Ether, manufactured by the action of sulphuric acid upon alcohol, furnishes an anæsthetic preferred by many to chloroform. It is a stimulant and antiseptic, and sometimes may be found useful for hypodermic injection when collapse is threatened. For inhalation in angina pectoris, asthma, etc., it is often a valuable agent.

Sulphurous Acid has one equivalent of oxygen less in its composition than sulphuric acid, and may be written down as a gas held in liquid solution. It forms sulphites, and is a very useful non-irritant antiseptic, particularly when employed for spraying sore throats. Produced in the combustion of sulphur it is largely utilised for the disinfection of apartments in which contagious diseases have occurred.

Sunstroke, loosen the attire and convey the sufferer into a shady place, applying the coldest water procurable, or ice if possible, to the head, which keep in an elevated position.

Suppository is a method of administering medicine by the bowel, usually composed of cocoa-butter softened down by olive oil and medicated to suit the case. Morphine, belladonna, nuxtonia, hamamelis, ichthyol, and other medicines, are thus introduced by suppository, and food is similarly administered when the stomach is in too irritable a condition to retain it.

Suppression applies in medical phrasing to the cessation of the secretions of certain organs. Such as of perspiration or of the urine or of menstruation.

Generally speaking it indicates the stoppage of natural, periodic, or other evacuation.

Suture, the junction of bones by their jagged margins, hence "sutured" and "sutural."

Swine Fox is one of the varieties of Chicken Pox, an infectious ailment, which see.

Syncope, or fainting, may be fatal when referable to serious affections of the heart or lungs. Attempts, when milder restorative measures fail, should be made to obtain a return to consciousness and functional activity by the employment of artificial respiration, the application of electricity, or the injection of ether or other quick-acting stimulants. In a simple faint, lay the person flat, with head low, and remove all clothing from neck and chest.

Synovial Fluid is secreted by the joint membranes for the lubrication of the cartilages, and for facilitating the movements of the bones, at their junction with each other. The synovia is formed of oleaginous and albuminous matter called in popular parlance "joint oil." When the synovial membrane is in any wise inflamed the fluid will often be excessively secreted, giving rise to painful swelling, as in "housemaid's knee," and should the joint become organically diseased, and chronic inflammation be occasioned, there is apt to be a general degeneration of tissue, in which the synovial membrane participates and helps to form such a permanent abnormality as is specially shown in the knee joint when white swelling appears.

Tamarind. The preserved pulp of the pods of the tamarind tree of the Orient yields an agreeable laxative acid substance, of great use in inflammatory and putrid disorders, for abating heat and thirst and correcting putrefaction. Tamarind juice and tamarind tea are both admirable anti-febrile drinks.

Tannin is the astringent principle of oak-bark and galls. Tannic acid is employed medicinally to stay hæmorrhage, to constrict relaxed tissues, and to check excessive secretions. The preparations principally used are the tincture of galls, the tincture or compound powder of Kino, and the tincture or compound infusion of catechu. Tannin combined with glycerine may be painted upon the tonsils advantageously as an astringent in badly relaxed sore throat.

Tapeworm in the intestines is the result of absorption from infected animal food of the un-developed forms of the parasite, or they may be taken into the human stomach with celery or salad. Once in the human intestine the tiny larva of the tapeworm proceeds to final development. Hatching out, it attaches itself, by tiny hooks in its head, to the membrane of the alimentary canal, and grows downwards by budding, in detachable segments, each capable of the reproduction of their species, to a length as much sometimes as 20 feet. Naturally the presence of tapeworm is irritant in the extreme, and perhaps the best way to get rid of the pest is by treatment with naphthaline, which appears to act as a direct poison to it. Chloroform water has a paralysing effect upon the worm, causing it to be sold on the membrane, when purgation will cast off the parasite with the evacuations. Until the minute head of the worm is detached and voided the cure is incomplete, for any number of new segments may be developed. A simple cure is to fast for 8 hours, then to take at night a drachm of water fern extract, with mucilage and pepper-mint water, a dose of castor oil in the morning, and a plate of mashed potatoes at 11 a.m.

Tapping is the surgical operation resorted to for the removal of fluid collected in quantity in any of the cavities, as of the pleura or abdomen in dropsy. It affords immense relief. Tapping of a minor nature is surgically undertaken for the extraction of superabundant fluid from joints, extensive watery tumours, and large abscesses.

Taraxacum, the medical term for the dandelion, largely employed in pharmacy, chiefly as an adjunct to other drugs. In decoction, extract, and juice it forms an ingredient of pills and potions remedially used in indigestion due to liver torpidity.

Tartar Emetic, the tartrate of antimony and potash, a colourless crystalline salt, soluble in water. It has expectorant properties, and produces a powerfully depressing effect upon the heart's action.

Formerly it was a good deal used in febrile attacks, but is not now so much favoured medically. It is a deadly poison if taken in too large doses, and is employed externally in ointments as a counter-irritant where "white swelling" exists.

Tartaric Acid, the characteristic acid of the grape, exists in various vegetable products, and enters into the composition of cooling effervescent drinks and some medicinal preparations, as the sedilite powder: colourless and without smell, it is peculiarly sharp and "tart" to the taste.

Tartrate of Potash is a mild and efficient purgative, and when given with more powerful aperients, like senna, counteracts their griping properties by accelerating their action.

Tendons are the strong inelastic cellular bands by means of which the muscles are attached to the bones. They are often expressively styled "leaders," and present the appearance of white glistening cords endowed with great strength. The Achilles tendon on the heel—capable of resisting a force equal to a thousand pound weight—the tendon of the diaphragm, and those of the groin, hands, and feet are the most noticeable. Most of the tendons are subject to sprain or rupture, and in the latter case call for surgical treatment. **Terebene**, a colourless volatile fluid, slightly resinous in smell, is procured from turpentine by the action of sulphuric acid under heat. It is useful in bronchitis, five to ten drops on a piece of sugar, and makes a soothing inhalation in inflammatory affections of the respiratory organs. Terebene possesses antiseptic properties, and has been employed in wound dressing. Terebinthina is the oil of turpentine, employed in the manufacture of certain soaps.

Tertian, occurring every third day, as tertian fever, tertian ague, etc.

Tetanus, the technical term of lockjaw.

Tetter, a common name for the skin ailment technically termed "herpes," and also applied to eczema as "dry" and "wet" tetter.

Therapeutic, curative; hence the branch of medicine devoted to the treatment of disease is styled therapeutics.

Thorax, the chest cavity and its bony framework. The conical-shaped thorax, narrow at its summit and broad below, contains the heart and the large vessels therewith connected—the lungs and their bronchi, a portion of the windpipe, the œsophagus, the thoracic duct, and many important vessels, nerves, and glands. It varies in circumference considerably according to the robustness of the constitution; but when properly developed in the adult, should average from 35 to 38 inches, and should be well rounded, neither too flat nor too sharp—bulging to the "pigeon-breasted" formation, which often follows a rickety childhood. The contracted thorax is characteristic of the consumptive tendency, whilst the deep and expansive chest is usually indicative of urgent respiratory power, though overprominence means emphysema of the lungs.

Trismus, a very painful neurotic affection of the face and side of the head, paroxysmal in character, and generally most troublesome in the temporal nerve. Phenacetin is recommended for the immediate relief of the most distressing symptoms, while quinine and nourishing dietary are likely to conquer the neuralgia. One peculiarity of tic is that there is nothing to show the poignant pain, no swelling or redness. This differentiates it from ailments of rheumatic origin. It will come and go with startling suddenness too; sometimes being induced by the slightest touch of the nerve or the most momentary exposure to draught, departing after inflicting excruciating torture abruptly. Emotional and highly-strung persons of indoor occupation are more subject to tic than others.

Tinctures are solutions of numerous drugs in spirit, specially suited for their infusion. Proof, rectified, or aromatic spirit of ether is employed in pharmacy for the production of certain tinctures, not only for its solvent properties, but because of its anti-spasmodic virtue; and aromatic spirit of ammonia for its alkaline quality. Proof spirit is used when the active principles of the drug required remedially are soluble partly in water and partly in spirit; and rectified spirit is

preferable when the drug is but sparingly soluble. All the more common medicinal tinctures are referred to in their alphabetical order, or in connection with the ailments to which they are applicable.

Toe Nails, Care of. The toe nails require to be always clean, well trimmed, and free from compression. Should any indication of abnormality, or of disease in the surrounding tissue appear, advice should be secured without delay and acted upon. (See *Nails*.)

Toes. The toes are liable to fracture, to affection by painful corns, bunions, and to gangrene in senility, as elsewhere noticed. Splints are most necessary in toe injury, as bandaging the neighbouring toes together will give the necessary support.

Tongue. The organ of speech and taste, is a ready tell-tale of health or its converse. To the eye of experience it reveals at a glance the state of the digestive organs, and indicates any disturbance of the general system. Should the tongue be swollen, with accompanying throat catarrh, we have the sign of stomach disorder; a dry tongue points to prostrate strength; furless and red signals intestinal irritation; heavily coated with white fur it announces a febrile bodily state; relaxed it speaks with sympathetic silence of rheumatic trouble; protruded and pointing sideways it indicates partial paralysis, and the situation of the palsied part; strawberry-like it assists in the diagnosis of scarlet-fever. It is liable to many ailments of its own, besides thus by its dryness, moisture, bulk, movements, and the character of its coating affording the index to derangement elsewhere. Ulceration, inflammation, and cancer at times assail the tongue, and demand remedial treatment of a proper character with a pre-emptiveness which will brook no denial. The exquisite sensibilities of touch and taste in the tongue are admirable aids to the direction of the all-important processes of mastication.

Tonsils. Two rounded almond shaped glands reared immediately behind the anterior pillars of the soft palate on either side of the throat, secreting a tenacious mucous fluid. These glands very often become enlarged in childhood, from various causes, and may be surgically reduced or even extirpated without detriment to the future development of the patient. In tonsillitis or inflammation of the tonsils the murate of calcium is a very valuable curative agent; but indications of this ailment should always receive early medical attention, as they frequently point to rheumatic trouble.

Tooth. A tooth consists of cement, dentine or ivory and dental pulp, the whole covered with enamel. The exposed portion above the gum is called the crown, that within the socket the root, and the narrow part intervening between the root and the crown the neck. See "*Cutting of Teeth*."

Toothache. "There never was yet philosopher that could endure the toothache patiently." Shakespeare made Leon sapiently to say in "Much Ado About Nothing." But as toothache does not kill it is made light of by all save the sufferer for the time being. Arising almost always from decay, it may be remedied by the removal of the troublesome tooth, or it can be stayed by the dentist in the early stage of manifestation frequently by skilful stopping. Pain, too, may be assuaged by cleansing the cavity and introducing a pledget of wool saturated with dilute carbolic or cocaine. Should neuralgia or digestive disorder be the exciting cause of a bad toothache bout, as both often are, temporary relief may be secured by overcoming the nerve trouble or setting the digestion right; but sooner or later toothache will take its subject to the dentist if he or she be wise.

Torpor indicates injury to or disease of the nervous system, and unless the semi-comatose person can be roused by ordinary restoratives, a very grave condition is plainly existent. Such torpidity calls at once for the doctor's assistance.

Trachea. Is that part of the windpipe between the bronchial tubes and the larynx or organ of voice. Liable to inflammatory ailments, it is the portion of the air passage surgically opened in the operation of tracheotomy when suffocation threatens from diphtheria and certain other malignant throat affections. (See *Bronchotomy*.)

Trance is an abnormal condition which, without

being either sleep or swoon, involves suspension of the voluntary functions of the body, while therein the mind sees visions. One subject to trance is a "passive resister" to all attempts at restraint, but may often partake of and assimilate administered nourishment. (See *Catalogue*.)

Transfusion. the injection of the blood of one animal into another; sometimes the blood of a healthy and vigorous subject is introduced into the vessels of another person in a condition of collapse as an extreme restorative resource.

Tremor. or involuntary shaking, is a symptom of nervous debilitation arising from undue excitement, exhaustion or actual disease. In fever it indicates great vital prostration, and is a very frequent accompaniment of paralysis and of urebriety.

Trichinosis is a disease—happily infrequent—due to the invasion of the muscles of the human organism by a minute worm called the trichina spiralis, introduced by eating the infected flesh of pigs, or other animals therewith infested. The disorder sets in a few days after partaking of the infected meat, and its symptoms have considerable resemblance to those of typhoid fever, with which no doubt it has sometimes been confounded. After trichinosis has run its most favourable course—for it is not necessarily fatal—the microscopic worms may become encased in the muscles and thus remain embedded, causing no further mischief. The disease requires the most urgent and skilful treatment.

Trunk-Pack is sometimes resorted to in the hydropathic treatment of febrile conditions of the abdomen and thorax, its object being to induce free perspiration coincident with a general reduction of the temperature, obtaining by the aid of saturated towels and many flannel swaddings, all the beneficial effect of a hot bath, without any of its inconvenience and dangers to a person in an enfeebled and precarious state.

Truss. an instrument largely employed for the support of the part by sufferers from rupture. It should always be well made, well fitted in every particular of pad, spring and straps, whether single, double, or bag shaped. (See *Rupture* and *Hernia*.)

Tubercle is directly due to the presence within the system of the tubercle bacillus, which is the organism or disease germ known as the tubercle bacillus. Tubercle attacks the lungs, certain glands, and the bones, and destroys their vitality to a greater or less extent, usually spreading its ravages to the tissues of the body. It cannot flourish under healthy general conditions, and may sometimes be counteracted and driven out of the system by vigorous medical treatment, commenced before the malignant bacilli have obtained too great a hold. The murate of calcium alone or in combination with hyposulphites is very antagonistic to the destructive bacillus which is the active occasioner of consumption.

Tumours are abnormal growths upon or within the body, varying in size and significance from a wart to a malignant cancer. Thus every adventitious excrescence, boil, abscess, wen, polypus, or cancer, is, strictly speaking, a tumour, but not every tumour is a cancer, nor every cancer malignant. Tumours usually require at some time or other surgical attention and they are often successfully removed by operative treatment from the breast, throat, abdomen, larynx, and even the brain, so that sufferers from tumour or their friends need not necessarily take a pessimistic view of their ailment. A tumour of any considerable size wherever situated of course requires expert examination, and will be dealt with according to its particular nature. "Tumid" signifies enlarged or distended, and "tunefaction" is a longer name for a tumour or swelling.

Turkey Rhubarb. The term usually applied to the best kind of medicinal rhubarb in the market, though it does not by any means always emanate from the domain of the Sultan.

Turmeric. obtained from the root of the curcuma, an Oriental member of the ginger genus, forms an important ingredient in curry powder composition, is useful as a means of making chemical tests for alkalies, and finds limited employment in medicine as a stimulant. In India doctors use it sometimes for colic or cramp.

Turpentine is a spirit derived from the resinous

exudations of certain species of pine tree; and possesses many very valuable medicinal properties. Applied externally upon a hot fomentation it is a powerful counter-irritant to spasmodic and inflammatory affections of the abdominal viscera; and it is often remedial in similar treatment of rheumatic attacks of the muscles, nerves, and joints.

Tympanum, the cavity of the middle internal ear in which lies the tympanus. (See **Ears**.)

Typhoid, a synonym of enteric or gastric fever, is a condition of the system entailing very considerable peril to life, and consequently always properly regarded with gravity. (See **Enteric**.)

Typhus Fever, the Black Plague and jail fever of old, is an infectious and pestilential malady arising from a vitiated atmosphere and general insanitary surroundings. Characterised by much pain, excitement, and delirium, it is therefore often spoken of as "brain fever" and "camp fever." Its characteristic eruption, resembling somewhat the spots of measles, and interspersed with what look like flea-bites, is different from the slightly raised rose-coloured and typical rash of typhoid, which disappears on pressure with the finger.

Typhus is variant again from typhoid or enteric in that the latter's most malignant influence is located in the bowel chiefly, whilst the stress of typhus is on the brain. One of its earliest manifestations is severe headache, followed by delirium, sleeplessness, dreadful dreams when fitful slumber is obtainable, twitching of the muscles, and subsequent coma. Usually the bowels are confined, quite an opposite condition to that obtaining in typhoid. Again, typhus has no definite duration like typhoid, but generally begins to decline, should its course be favourable, in about fourteen days, though many cases have lasted much longer. On improvement taking place—upon the fifteenth day or thereafter, as the case may be—recovery is frequently sudden and most marked. The treatment requisite is the admission of as much pure air as possible to the apartment in which the sufferer is confined; most assiduous and watchful nursing, keeping the bowels open, the application of ice to the head in delirium stages, blistering at the back of the neck if necessary, support in the shape of beef-tea and milk, with port wine and brandy should the prostration prove excessive. Sometimes there is distressing cough and chest disturbance, which should find relief in the application of mustard plaster; but this belongs to the essential careful nursing, as does the requisite judgment when to withhold or administer stimulants. Disinfectants must be used to obviate contagion all through.

Ulcer. A sore on any soft part of the body, attended with pain, inflammation, and the discharge of pus, and destructive, at least for the time being, of the tissues of the skin or mucous membrane. An ulcerous condition means literally one in which there is an eating away of surface, and is due to the circumstance that the healing of a wound or sore of any kind has been prevented by the development of the genus of decomposition which have invaded the injured part. Ulcers therefore call for antiseptic treatment, wherever situate, to destroy the vitality of the malign agencies at work within and connected with them. The sooner and the more thoroughly this is undertaken the quicker they will cease to trouble. They should be cleansed and supported, preserved from irritating friction, and dusted with iodoform or aristol to expedite their healing.

Ulna. One of the two bones of the forearm, between the elbow and wrist, sometimes styled the cubitus. It lies to the side of the little finger when the arm is held palm upwards.

Umbilicus. The navel, hence unibellical cord, the navel string.

Urea. A substance of nitrogenous pro-duction contained in the urinary secretion and excreted by the kidneys. When the diet is largely composed of animal food the urea is increased in amount, and diminished by vegetarian alimentation.

Uræter. The tube or duct conveying the urinary fluid from the kidneys to the bladder. When, as it sometimes does, it becomes the seat of intense pain, through the presence or passing of renal calculi, the anodyne treatment recommended is hot fomentation

upon the textile medium of the application, and coincident subcutaneous injection of morphia.

Urethra. The canal from the bladder by which the urinary secretions are voided. It is liable to numerous distressing ailments, which are frequently "quacked," and mostly to the misery of their unfortunate subject. A competent practitioner should always be consulted without delay in affections of the urethra and any of its associated organs.

Uric Acid. Sometimes called also lithic acid, a urinary product, affording urates, and a source of the calculi which occasion such serious bladder disturbance on their accumulation within that organ.

Urine. This secretion of the kidneys conveys from the body in a liquid form certain products of decomposition. It is, in health, of a light amber hue, of an acid reaction, and very slightly in excess of the specific gravity of pure water. An average adult excretes 24,000 grains daily, in which are dissolved so to 12 grains of uric acid, and 500 grains of urea; but the amount of water passed varies according to season and circumstance greatly. Thus the urine is lighter and much more abundant in cold weather, when the pores of the skin are exuding little moisture; but, in high temperature, when there is heavy perspiration, urination is scant, highly coloured, and comparatively frequent. When it is more odorous than the common it indicates that decomposition has been going on; if it contain dark, dull brown blood, the condition points to hæmorrhage in the kidneys; a red or dark colour of the water tells of bleeding in the bladder coat or the prostate gland at its base; an excess of urates tells of the existence of gravel; a brick dust-like deposit is associated with rheumatism; sugar with diabetes; these and other abnormalities in the evacuated water are all powerful aids to the physician in the diagnosis of disease. Difficult or painful urination should always have early medical attention.

Uva Ural, the bearberry, is a North European plant, the leaves of which are largely used medicinally for their astringent properties, and the infusion thereof is prescribed for bladder irritability.

Uvula, the small tongue-like and spongy extension suspended from the upper portion of the soft palate between the tonsils. When elongated abnormally it creates irritation at the top of the larynx, exciting a peculiar kind of cough, and may require surgical reduction to yield relief, though sometimes the trouble may be bargained away or palliated by suitable inhalations. The uvula is a participant in the pain endured by gummy, sore throat and scarlatina.

Vaccination is compulsory by law in this country in the case of infants between birth and the age of three months, unless an objecting parent or guardian can persuade a magistrate to grant a certificate of exemption on conscientious grounds, generally a difficult matter, and the request is preferred in only a comparatively insignificant number of cases nowadays. (See **Small Pox**.)

Verrucal Root, very disagreeably odorous and nauseous to the taste, is used in infusion and tincture for the treatment as a stimulant and antispasmodic, of hysteria, epilepsy, St. Vitus's dance, and other nervous affections.

Varicella, the medical name of Chicken Pox, regarded as a contagious disease, though in itself usually of a mild character, capable of being conveyed by infection to a second person, in whose case a more virulent attack may be experienced.

Varicose Veins, the most frequent position of varicose, or swollen and knotted veins is the calf of the leg, but they may appear elsewhere, and are not uncommon in the region of the anus, when they take the form of or occasion piles (which see). They may arise from age or debilitation, from over strain in standing, from wearing tight garters, and from pressure during pregnancy. When swelling and inflammation accompany varicosity, loss of bleeding and ulceration may ensue. Bandaging and the use of elastic stockings are recommended, and sometimes operative treatment may be necessary.

Veins. After the blood from the heart has passed in the course of the circulation all along the gradually attenuating arterial system, it is taken up by the

capillaries, which, becoming larger and larger, end in the veins. The veins growing more and more expansive on route, join to the main large trunks or vessels through which the blood is conducted back again to the right side of the heart whence it first flowed, to be purified in the lungs for retransmission. The veins are supplied with valves opening forward only, and thus preventing any ebb of the blood. They are liable to distension when pressure is exerted by any abnormal cause upon any part nearest the heart than that affected, giving the condition of varicosity. (See **Varicose Veins**.)

Vegetarian Dietary, in the ordinary conditions of human life, would be insufficient alone to support the functions in vigorous activity and repair the regular wear and tear; that is to say, a mixture of animal food is conducive to the well-being of mankind. On the other hand, vegetable aliment cannot be dispensed with without injurious consequences. Those vegetarians who refrain from animal food on account of their humane repugnance to the destruction of life practically admit this when they partake of nutritious animal products like milk, eggs, butter, and cheese.

Ventricle is the name given to various cavities of the body, as of the brain and the larynx, but more particularly to the chambers of the heart from which is distributed the blood, the left ventricle supplying the circulation to the body, whilst the right keeps the flow to the lungs. (See **Heart**.)

Vertebra. This is the scientific term applied to the bones forming the spinal column. (See **Spine**.)

Vertigo is a symptom which should always be viewed with apprehension, as it very frequently indicates mischief within the internal ear or in the brain itself. (See **Giddiness**.)

Vinegar is, in small quantities, good. It supplies a salutary and grateful stimulus to the stomach, correcting the flatulency of vegetable food and the putrescency of animal aliment. But any excess of it is pernicious.

Vitreous Humour. The pellucid liquid which fills the bulk of the eyeball behind the crystalline lens.

Vitriol. Vitriolic acid, or oil of vitriol, is known in chemistry as sulphuric acid, which is employed medicinally in a guarded way. (See **Sulphuric Acid**.)

Vitus's Dance, St. (See **Chorea** and **St. Vitus's Dance**.)

"Wall" Eye. A condition in which the iris is almost destitute of colour, or bluish-white or greenish appearance, as the case may be.

Warm Bathing is not only essential to cleanliness, but the best of all bathing for health and comfort's sake. A temperature of 70 to 80 degrees gives a sensation of warmth to the skin, and obviates the shock induced by a bath at anything below 60 degrees in temperature or the excessive stimulation resultant from plunging into and retaining the body in water heated to 85 degrees and upwards. Many people are apt to remain over long in a very warm bath, which is exceedingly and positively dangerous to anyone with all defective heart action, besides giving great susceptibility to cold through the opening of the pores effected by heat and immersion. Soap of pure composition, and impregnated with just the requisite amount of alkali and no more, such as can safely be relied on if bearing the name of **Pears**, is necessary to complete healthful luxury of a properly regulated warm bath, removing as it does all the fatty matter exuded by the oil glands. A cold sponge before a brisk towelling before dressing will tone up the skin and system and set the bather into a glow.

Warts are irregular horny excrescences of the outer skin, occurring chiefly on the fingers and hands, but sometimes on the face, neck, and ears; and occasionally also, of a softer nature, upon the mucous membranes. These thickenings of the cuticle, which, at times, are of considerable size, and may involve a portion of sensitive upper surface of the derma or true skin, with its minute blood-vessels, are always unsightly and inconvenient. They may, however, be readily extirpated in most cases by paring or scraping the surface daily, and touching with a stick of lunar caustic; strong acetic acid, or chromic acid, will sometimes suffice to destroy them. If these fail, nitric acid, applied through

a glass tube, so as to protect the surrounding tissues, may be tried. Sometimes they resist treatment, and yet suddenly disappear spontaneously later on in a very puzzling fashion. If pedunculated, they may be slipped off by sharp scissors, or tied round tightly with strong silk, which often brings about their separation insensibly in a short period. Epsom salts taken twice or three times a day for a little while will check, and generally cure the tendency in children to wartiness of the skin.

Water in the Abdomen, technically termed **Ascites** (which see), or abdominal dropsy, is an accumulation of serum in the cavity, caused by obstruction to the flow of blood within the veins; such obstruction being the product of diseased conditions of the liver, kidneys, heart, or a consequence of inflammation of the peritoneum. Tapping affords relief, great relief; but the water will again accumulate if the disease that occasions it continue, until the patient succumbs in the end to exhaustion. Medicines acting on the circulation and secretions may mend matters meanwhile, but continuous abdominal dropsy is difficult to overcome.

Water on the Brain. This is always a serious, and generally a fatal, disease, its origin being tubercle, often inherited. Frequently, too, it follows meningitis.

Weaning. Till the appearance of the first or milk teeth, infants should, wherever possible, be fed entirely by suckling; but after Nature's indication that the child can eat of itself, rusk and farinaceous food may begin to be given. The weaning should commence in the ninth or tenth month; artificial feeding being increased in frequency and quantity of administration as the breast is being gradually withdrawn. Not more than about three ounces of fluid should be fed to the child at any one time, lest its stomach be overloaded, and the digestive powers impaired in their early development. Give thus at regular intervals, with nothing in between, and see that the baby's bowels are kept open. If the maternal breasts become painful upon weaning gentle saline aperients should be taken, and the mammary glands bathed with cologne water lotion.

Wens. These are small tumours, sometimes peduncular, sometimes egg-shaped, elastic to the touch, smooth, and shiny. They consist of yellow, cheesy-looking matter, enclosed in a cyst or sac. They are caused by abnormal enlargement of the sebaceous glands of the skin, and appear on the head, face, neck, and other parts, reaching any size between that of a boy's toy marble to an orange, or even larger. They are harmless, and are best left alone if not so large as to occasion serious inconvenience or implicate other structures. Surgical treatment should aim at entire extirpation of the sac, but there is always some danger of erysipelas following the operation.

White Leg or Phlegmasia Dolens is a painful condition arising sometimes after confinement through absorption of fetid matter. It is due to inflammation in the veins, producing coagulation and obstructing the return of the blood to the heart. The consequence takes place into the tissues, and a tense, swollen and glossy brightness of the skin ensues. There must be perfect rest in the recumbent posture, hot fomentation, and careful attention to the bowels, with a simple and nutritious dietary, while five-grain doses of the iodide of potassium three times daily may be administered with good effect.

White Swelling is the common term of a disease of the knee joint in which degeneration of the synovial membrane and cartilage has taken place as a consequence of prolonged inflammatory irritation. The limb must be placed in splints, perfect rest enjoined, and a dressing of mercurial ointment applied, the general constitutional health being built up as much as possible coincidently. If the patient can be given a change to the seaside air all the better, for white swelling nearly always argues bodily debility.

Whitlow is a painful affection on the thumb or finger deep down in the tissue due to blood-poisoning. The bone, tendons, or strong muscles may be the seat of the suppurating trouble, and the pus often has such difficulty to find an outlet that it will remain until most offensive, and finally escape by the sides of the nail, at some distance from the actual ulceration. There

will be great pain, heat and throbbing. Poulticing, persistent and thorough, is requisite, to get the matter away, and lancet used very liberally will be necessary to clean out the wound completely. The general health should at the same time have medical attention.

Windpipe. The windpipe, except when swallowed always open at the top, is a rigid tube, distended by thick plates and rings of gristle or cartilage. It is a hemispherical tunnel, running from the larynx to the bifurcation of the bronchi, down the front part of the neck, dipping behind the breast bone into the chest. The back part of the tube is flattened and flexible so as to yield to the passage of food and drink down the gullet or food pipe immediately behind. The windpipe or trachea is liable to inflammatory affections like the rest of the air-passages, which are soothed by the inhalation of steam, impregnated with anodyne and antiseptic substances, while hot fomentations and poulticing externally will frequently afford relief. (See *Trachea*.)

Worm Bark. This is the bark of the cabbage-tree, used sometimes as a vermicide, but is not to be recommended because of its uncertain inaction, and is not altogether a safe thing to take.

Worms. Worms are very troublesome to some children, setting up irritation of the intestinal canal they infest, and working much constitutional mischief if not extirpated. The symptoms of their presence are variable and vitiated appetite, foetid breath, grinding of the teeth, picking and itching of the nose, pains in the stomach, disordered bowels, and irritation of the rectum and anus, with passage of the parasites in evacuations. Round worm has resemblance, as far as shape goes, to the common garden worm; thread-worms are thin, short, and white, and inhabit the rectum or lower part of the large bowel. Tapeworms (which see) are enormously long and many jointed, and capable of reproducing detached segments until the head is dislodged. The latter often trouble the adult, and the treatment is described elsewhere. Calomel and scammony, santaline, and other vermicides, are employed for the expulsion of the round and thread-worms, after previous emptying of the bowels, a free purgation again following the elected medicine. Injection of salt and water or infusion of quassa is used to kill threadworms.

Wounds. A clear cut or incised wound, as with a razor, if not extensive, will usually heal readily by being brought together by means of strips of adhesive plaster of a non-irritant nature, small intervals being left between the strips to permit of the escape of blood or serum. Antiseptics ought first to be applied in this case and in every other class of wounds, &c. dirt being thoroughly removed from the wound. Should the wound be long and deep, its edges may be stitched together neatly with white silk and a glover's needle all along, both needle and silk being sterilised before use by saturation in dilute carbolic acid or some other antiseptic. Should any artery or other important vessels have been severed, they will require sewing to stop and prevent further hemorrhage, pressure being exerted to allay bleeding meantime. Wherever extensive hemorrhage exists, surgical assistance should at once be sought. A wound made by a blunt instrument or caused by a fall is generally contused and lacerated, presenting torn, rough or jagged edges. Gunshot wounds sometimes come within this category. Injuries of such a character require cleansing of clot and blood and any dirt foreign matter which may have been introduced. After treating with antiseptics, dressing with carbolic oil is most suitable usually in these instances, being readily renewable. Amateur surgery should never be attempted in serious wounds wherever a qualified practitioner is available.

Writer's Cramp. A painful affection which sometimes attacks those who are condemned to labour continually hard with the pen, sometimes styled "Scrivener's Palsy." It comes of over working one set of muscles. It has analogy to ailments suffered by compositors, pianists, tailors, seamstresses, violinists, engravers, and telegraph operators, and arises from a like cause. Sometimes electricity has been successfully employed for its relief.

Wry Neck, in which the neck is twisted or turned awry, arises from a spasmodic contraction of the sternomastoid muscles which chiefly govern the movement of the head from the side. Should a baby be born with this deformity it is remediable by surgical operation; and if the condition be the result of accidental injury or burning it will also admit of amelioration at the surgeon's hands. Wry neck due to paralysis of the muscle on one side will require special restorative treatment, and if rheumatism be the cause then the inflammation must be combated and a liniment of a stimulant nature applied. Cotton wool and an oiled wrapping should be placed to the part after each rubbing in of the liniment.

Xerasia, a disease of the hair, which becomes dry and ceases to grow when affected therewith.

Xeroderma, a morbid dryness of the skin, in its severest form constituting fish-skin disease.

Xerodes, a kind of tumour, attended with dryness.

Xerophthalmia, a dry red and itching ailment of the eyes.

Yam, the Dioscorea, on whose big tuberous roots John Chinaman and many natives of the East Indies live as much as we do upon potatoes, furnishes a nutritious article of dietary.

Yaws, a cutaneous ailment, common in Africa, the West Indies, and tropical America, commencing with eruptions upon the face, under the armpits, and on the groin. It is contagious and proceeds to ulceration of a very untractable and weakening character.

Yellow Spot in the retina of the eye is the sensitive small central place in the direct line of vision, and is so called from the yellow tinge it assumes after death. When one looks at any object one moves the eye about until the image of such object is reflected directly upon the yellow spot of each eye, thus giving single vision with two eyes.

Zinc. Zinc is a metal which does not usually occur in Nature as such, but is obtained from its ores, chiefly the sulphuret and carbonate of zinc. It is much used medicinally in various ways, both in oxide, chloride, and sulphate. The oxide is a white tasteless powder, largely employed in ointment making; and this preparation or the valenianate of zinc are given internally for epilepsy and St. Vitus's Dance. Sulphate of zinc, or white vitriol, looks very like Epsom salts. It is used a good deal in the making of eye lotions and also provides a very powerful and urgent emetic agent productive of immediate vomiting in poisoning. The chloride of zinc is caustic and antiseptic, and is serviceable in the destruction of unhealthy and malignant growths.

Zinc Lotion, as applied to burns and scalds for emollient and healing purposes, is made of sulphate of zinc, one drachm, diluted in a pint of water. It arrests discharges from the wounded surface, and affords considerable relief.

Zinc Ointment, so valuable in eczema and in ulceration generally, is made by rubbing well together an ounce of the oxide of zinc and six ounces of pure oil, adding one part of carbolic acid to twenty of the ointment. For use with children and in all ordinary cases of watery discharge or suppuration after injury, this is one of the best of healing ointments.

Zizyphus. A shrub chiefly found in tropical regions, one of the varieties of which is supposed to be identical with the lotus, or lote tree of old Egyptian mythology. Zizyphus nummularia furnishes a fruit yielding an astringent essence used in India for bilious disorders, and the bark of Zizyphus jujuba is remedial in diarrhoea. Other varieties of this plant are very largely used in medicine in different parts of the world.

Zygoma, the cheek bone or arch, the arching process projecting from the temporal bone, to which are attached the fleshy fibres of the temporal muscle; the sutures uniting the two contiguous bony formations are technically termed zygomatic.

Zymotic means infectious or contagious, implying reference to such diseases as may be inoculated and are of an epidemic nature. Scarlet-fever, smallpox, chicken-pox, measles, typhoid, mumps, diphtheria, erysipelas, and cholera are all zymotic, and to a considerable extent are resisted by sanitary precautions.

PEARS' DICTIONARY
of
SPORTS & PASTIMES.

EDITED BY
C. B. FRY.

Founder and Editor of "Fry's Magazine," "The Book of Cricket," &c.

Pearš' Dictionary of Sports and Pastimes

INTRODUCTION.

By C. B. FRY.

Founder and Editor of "Fry's Magazine."

It must be understood, of course, that in a compendium of the present nature there is no scope for the detailed technology and the elaborate rules of sports and pastimes, such as Cricket, Golf, and Lawn-tennis among outdoor subjects, or of Bridge, Chess, and Billiards among indoor subjects, which have developed into specialised cults. But the main characters of these are adequately described, and whoever wishes to pursue the study of a particular subject among them in minute detail will find a wide choice of books which may be consulted. The less popular and un-specialised sports and pastimes, however, are treated almost as completely in these pages as the (supposedly) more important; and it must be remembered that really the relative importance of each subject is a matter of fashion and individual choice and is not to be measured by their spectacular importance, which decides the amount of space devoted to them in the columns of the daily papers. A game may be a very good one for play and a very poor one for news; and publicity is no true criterion of the value of a game to those who actually play.

It seems to me that the second division of this Sports and Pastimes Section, which deals with Indoor Games, is particularly useful, for these include subjects upon which information is continually in request, yet is generally unavailable in the form of a book of reference. Considering how much attention is given among us to outdoor pastimes, one is often surprised that indoor games have not been cultivated with a similar regard to the possibilities of this or that pursuit. To my mind there is no doubt that much good would come from the exercise of more ingenuity in the adaptation of some outdoor pastimes to indoor conditions; and I am inclined to agree with that enthusiastic reformer, Mr. Eustace Miles, in his opinion that, where at all possible, one room in the house (he says the largest and the best) should be a "Games Room," equipped with facilities for physical exercise, not only in the form of gymnastics and so-called physical culture, but in the form of suitable adaptations of games. There is a kind of cricket that can be played indoors, and a species of rackets and of fives. Perhaps not the least value of the following pages is that they may suggest to ingenious minds the possibility of such adaptations. But it should be remembered that the exercise of ingenuity in such a way produces a result much more interesting than the mere execution of detailed advice set forth in thought-saving detail.

There is a peculiar fallacy connected with Sports and Pastimes which is worth a few words of refutation. It consists in assuming that such pursuits are entirely outside the sphere of intellectual intelligence, an assumption which carries with it the error of tacitly regarding an individual as one person in his work and as another in his play. It is true that games of various kinds require various physical powers and adaptabilities, but such valuable qualities as observation, judgment, and perseverance are the same in golf and in chess as they are in business organisation and in the study of astronomy. Pastimes that require for success qualities intellectual, moral, or physical which are in themselves valuable, help to give us these qualities, or to develop them in us for all the purposes of life whatsoever. A persevering character comes from activity with perseverance, and whether the activity occurs in the sphere of sport or of work is after all not very material. If you are a thoroughly persevering cricketer, you are more likely to be a persevering man of business than if you ceased trying in this game the moment any difficulty confronted you.

It may be of service, perhaps, to offer a word of advice on how to learn and attain proficiency in games of physical skill.

It is commonly remarked that such games cannot be learned from a book. But this is a half-truth and misleading. You can learn from a book how to do a thing; nothing but actual practice gives that co-ordination of eyes, brain, nerve, and muscle which constitutes actual skill. If a book can only tell you how to do a thing, at any rate you are then in a far better way towards learning to do it than you would be without that knowledge. A good book on a game is really as valuable as a good "coach," except that in consulting a book you have to supply your own brains, whereas in being taught by a "coach" you allow him to do most of the thinking. When it comes to it, no one ever really learns anything, except what he teaches himself, whether physically or intellectually. But a good book or a good "coach" can put you on the right road and point out safe short cuts.

But the great secret of mastering all problems, whether of physical or intellectual skill, is to divide up the complicated whole into its simple parts and master each part successively.

Take, for instance, a stroke at cricket. In this the movement of the feet, the poise of the body, the action of the arms in taking the bat back and again in moving it forward constitute a complicated whole. But if one first of all learns by separate practice the correct movement of the feet, then the correct poise of the body, and then the correct arm-action, the separate practice of each simple part soon enables one to master the apparently complicated stroke. It is a sound maxim that difficulties disappear the quicker the more they are divided up. One might say that the first rule for acquiring skill is "Simple Division."

Then again, a point that is frequently missed in games of physical skill is that the correct mechanism of action can be learnt apart from the playing of the game itself. In a stroke in cricket there are two things, first the correct mechanism of action, and secondly the accurate timing of the ball. It is true that a good stroke requires both; the one is useless without the other in actual play. But that is no reason why the action should not be mastered first, by practice in a bedroom, at any rate to a certain extent, and then applied afterwards with a view to the acquirement of additional skill in timing. You can only learn to do a thing by doing it; but you can assist yourself much by first learning something that is subsidiary yet important. For instance, nothing is more valuable to a cricketer or a lawn-tennis player than the poise of body and quickness of foot that may best be acquired in dancing. Yet who would think of practising dancing in order to become a better batsman or lawn-tennis player? But whoever did so would be perfectly right.

With regard to Training and Fitness, these are long subjects, but they depend on two simple facts. First, there is nothing different between normal good health and athletic fitness except in so far as the heart is called upon to do heavier work in athletics than in ordinary everyday life. Secondly, specialised physical skill comes from specialised practice. In both cases training means gradual education: training is a process of building, not a plunge over a cliff. Any ill effects that come from the playing of the more vigorous games are in nearly every case due to violent strain without previous gradual preparation. It is a matter of common sense.

Finally, it is worth noticing that in nearly all games of physical skill sheer strength counts not much: what does count is the strength that consists in quickness and in accurate mechanism of action. It is, therefore, wise in all set exercises of the physical culture type to avoid those that are slow and ponderous and calculated to promote power. In lifting oxen or elephants, and to cultivate those that suggest rapidity, facility, and precision of movement. Quickness is of more all-round value in outdoor games than what is usually understood by the term strength.

SECTION I. OUTDOOR SPORTS.

Amusements on Shipboard. In the old slow-sailing days of sea-travel, organised amusements were essential to beguile the tedium of a lengthy voyage; but present-day steamers get so quickly from port to port that beyond a game or two at deck-quilts (constructed from rope), or a match at deck-cricket, within a netted enclosure, little in the way of open-air pastime is called for to supplement the concerts in the saloon and other social diversions of the floating hotel. For the children's entertainment, a swing is pretty certain to be fixed up, however; and generally a rope will dangle from some distance aloft to the upper deck, where with to play "swinging the monkey." A passenger grasps the rope with both feet and one hand, wielding a knotted handkerchief in his free hand. He is the "monkey," and, as he swings, the other players "cob" him with their knotted handkerchiefs, avoiding a blow from him as long as possible, for the player struck must change places with the "monkey." "Cock-fighting," hands behind and feet secured, upon a tarpaulin, or astraddle across a spar, has attractions for some.

Angling. Tersely, this sport may be defined as fishing with a rod and tackle, in pond, stream, or sea. The angling may be bottom-fishing, or with the bait

suspended at any distance between the bottom and the surface. Again, it may be fly-fishing, by casting the bait, artificial or natural, on the surface of the water, with that delicate manipulation which is the most artistic and delicate of all angling. The angler requires a suitable rod, line, hooks, and baits; in addition, it is desirable that he should be provided with reel, tackle, hook, landing-net, and creel or fishing basket. His rod may be stout and stiff for bottom-fishing, or light and flexible yet strong for fly-fishing; made in lengths, with adjustable joints. Bamboo and hickory are extensively employed in the making of the better rods; while good ash for the lower joints, and yew, lance-wood, and whalebone for the lighter lengths are frequently utilised. The hooks must be of reliable steel, well made, and of appropriate size for the class of sport engaged in; and the line may be fashioned from fine hempen twine, specially spun to endure immersion, or from cotton, silk, horse-hair, animal or silk-worm gut, separately or in combination. Floats of cork or quill (or both) are required, to regulate the position of the baited hook in the water, for all but fly-fishing, and this regulation must be assisted by weighting the line near the hooks with split shot or

other leaden attachment. Bait is chiefly either a favourite natural food of the fish angled for, or an artificial simulation thereof. Great skill is necessary in casting and controlling the fine line—with its hook-concealing, cunningly-constructed, artificial fly—used in angling for trout, salmon, and other wary fish; and arch practice and care are called for in striking and securing the finny prize. Experience is requisite to success in the less scientific under-surface angling also; and the sport is one that has fascination for many. See also *Sea Fishing*.

Archery, as a sport, is a survival of the use, for marksmanship exercise, of a very ancient weapon of warfare and hunting. Used by ladies and gentlemen members of modern archery clubs, bows may have a strength represented and reckoned in pounds, variant from twenty to fifty, and for long distances, even up to sixty-four pound power; while match bows average about 5 feet long, the extreme length for gentlemen being 6 feet, and the minimum for ladies 5 feet 3 inches.

are nine, seven, five, three and one respectively, the object of the archer always being to secure the "possibles" nine for a gold.

Aunt Sally is a game much favoured at country fairs, in which a wooden head is mounted on a pole, the fun of the thing being the endeavour to strike the nose of the figure with a short stick or club thrown from a given distance, and to break a clay pipe stuck into its mouth, or to knock off something lightly on the flattened crown of the conical head.

Badminton (or **Ladies' Rackets**) is a sort of scientific shuttlecock, played by two or four persons with light-meshed rackets and loaded shuttlecocks over an upright net, 5 feet high in the middle, and 5 ft. 4 in. at the sides, stretched between courts marked in a manner similar to that for lawn tennis, except that the size differs, and the service lines are very much nearer to the net than in the latter game. The "serve" is at Badminton diagonal from "server" to "striker out," and is made underhand, the racket in striking not

(Diagram of Ground as marked out for Badminton.)

The best are backed, that is, made of two or more selected strips of suitable wood compressed and secured together to give strength combined with elasticity. The choicest strings are of strongly twisted hemp. Arrows of lime-wood, tipped and triple-feathered, say a foot long, are used with heavy bows; lighter shafts of straight, seasoned deal will do for smaller bows. A brace, or shield of polished leather, hangs ready for use from the archer's bow arm; to the belt, on the right, is attached a pouch, or quiver, to carry the arrows: from the left side is suspended a green worsted tassel for wiping the arrow-heads. Gloves or finger-tips, complete the archer's outfit. Targets are constructed of twisted-circles of straw, sewn firmly with tarred string into flat disc shape, and covered with stout canvas. Four feet diameter is the normal measurement: the target stands on a light iron tripod at the chosen distance. The inner circle is coloured gold, and surrounded first by a band of red, then by one of blue, next by a black circlet, with the "outer" of white. Usually the points scored for hits

being raised above elbow height. Subsequent strokes by "server" and "antagonist" must all be volleyed over the net and into the opposing court. If the opponent fails to strike and return a proper service, "server" scores one; when "server" fails to send the shuttlecock over cleanly and within bounds, "striker" becomes "server." Points for game, with two or four players, are 15; i.e. the player or pair of players who shall first have fifteen aces registered to their credit wins. Should the score become fourteen all, one side must then score two consecutive aces to win. Badminton may be played on a lawn or in any hall or indoor court.

Ball Games are multitudinous in number, and have been from time immemorial. The classic Greeks practised ball-play of some kind or other as a health preserver, daily, either by throwing and catching, or by striking the sphere away with some part of the person or an aiding implement. Succeeding generations have adopted and elaborated upon the exercises and pastimes of their foregoers, as the

paragraphs both in this and the "Indoor Games" section show; balls of various sizes and weights, hollow as well as solid, being played with, along the ground, upon raised surfaces, and in the air.

Ballroom Ball. This is a game, very popular in France particularly, in which a large light air- or gas-distended ball is tossed from hand to hand for as long as possible without allowing it to fall to the ground. Inflated bladders were formerly used for the game; now light rubber is employed.

Bandy was the name of an old game in which many trace the beginnings of both golf and hockey (q.v.). It involved the striking of a hard ball by bands of opposing players with bent clubs or bats, towards fixed and opposite goals. The term "bandy" comes from the Anglo-Saxon *bendian*—"to bend"; and the wooden ball's fiftful course from side to side gave rise to the expressive phrase "being banded about."

Barleybreak, an old English running, catching and tugging game, now quite out of fashion.

Baseball. A glorified and systematised development of the old English game of "Rounders"—is now recognised in the United States of America as a distinctively national pastime. It is played—spectacularly by highly-paid professional experts, as well as by skilled amateurs—with a hard, leather-covered ball of tightly twisted yarn, over a rubber core, and a rounded wooden bat or club not exceeding 42 inches long or 2½ inches in diameter. Nine men constitute each side; one team takes the field, and the other goes in to bat. The pitcher of the out-side delivers the ball to the selected striker of the in side, who endeavours to hit it away to elude the fielders, and run round the bases home without being caught or put out by any fieldsmen, when one run is scored; should he miss three balls from the pitcher and the third ball be caught by the catcher, the striker is out. Upon three men being put out by catching or touching with the ball when off the bases, the fielding side go in; and after nine innings have been completed the side having registered most runs is declared the winner. The catcher stands behind the striker, to catch and throw to the basemen in the field the balls pitched to the striker; and all the fielding side need to be good throwers, swift runners and sure at a catch. The game is governed by very elaborate rules, and the umpire's position is a very responsible one. Baseball is played upon level expanses of turf, not less than 500 feet by 350 feet.

Basket Ball is a game played between sides of either sex, either in an open field or playground, or in a court 80 feet by 40 feet. The teams, five a side, seek to throw a round ball, resembling that used in Association football, into the goal-basket defended by their rivals; which is an open-work bag-net, a little larger than the ball, suspended from an iron ring fixed 10 feet high, and backed by a 6 feet square screen. No player must carry the ball, or hold it for longer than three seconds, or a foul is given to the other side, and a free throw at goal from 15 yards' distance ensues. Penalty goals count one, those got in legitimate play two points.

Battledore and Shuttlecock was a diversion of "grown-ups" as well as juveniles in the early days of the 17th century in England and Scotland, and princes played it. Wooden battledores, and very simple shuttlecocks, preceded the parchment-headed "drums," and leather-covered, balanced bottomed cocks with gaily painted feathers which gained a later vogue.

Beagles denotes the hunting of hares or rabbits by the aid of specially-bred dogs, named similarly to the sport they furnish. They are followed on foot, and afford excellent exercise "to the field." Our public schools and the juniors at the Varsity have kept up or patronised beagling for some years.

Bowling as a pastime has considerable charm, especially in the summer time, either on lake, river, or sea. To render it a safe recreation; reasonable care in embarkation and disembarkation, as well as changing place whilst on board, are requisite in the case of frail craft; and those responsible should know how to handle both the boat and the means of propulsion, whether rowing or sailing. As to the management of racing boats, see the articles on Canoeing, Rowing, Sailing, Sculling, and Yachting.

Boomerang, Throwing the. This is an art or diversion in which the Australian aboriginals were adept. The boomerang is a curved piece of hard wood or stick, flat on one side and rounded on the other; about 3 feet long, not more than three-quarters of an inch thick, and, say, a inches wide. The caster throws it upward with a sickle-like sweep, imparting rotatory velocity as it leaves the hand, when, after ascending to a great height in the air, the missile returns elliptically to near its starting point. The boomerang can also be manipulated so as to reach the ground in a downward direction at a surprisingly long distance from the cast, rebounding with ricochet motion, and striking the object aimed at by the skillful thrower.

Bowling, as distinct from "Bowls," or **Lawn Bowling**, and from an American variation of the pastime, flourishes yet as an outdoor game in many parts of England. Theorem what is sought to achieve is the bowling of a small, round heavy ball accurately, for a given distance, within prescribed limits as to direction, in a certain number of rolls or throws, according to prearrangement. Two antagonists, or a greater number, in sides, enter the contest, and the weight of the ball is employed varies from three pounds downwards to a few ounces.

Bowling (American). The bowling game most favoured in the United States is an adaptation of the old English alley pastime; and is played either in a prepared outdoor alley, or indoor court, with weighty bowls and pins, partaking, save in the shape of the missile, somewhat in the nature of skittles. Complications of an elaborate character have been introduced into the game, which has numerous local variations.

Bowls—Lawn Bowling, or Bowling on the green. Is a game engaged in upon smoothly-shaven turf by several single players, with heavy "blasted" bowls of lignum vitae or other solid wood. Often there are "doubles" at the game, partners taking turn in bowling at the white "jack" previously trundled to a judicious distance across the green, which is usually slightly convex in more than one direction. The object of the bowler is to bring his bowl to a standstill touching the "jack," or as nearly thereto as he can, and, incidentally, if need be, to remove the previously-bowled ball of an opponent to a greater distance from a winning position, or one sent down by his own partner nearer in. Points towards game are scored by the bowlers of the bowls lying nearest the "jack," when an "end" is completed; whereupon the "jack" is sent across the green—not more than twenty-five yards in Scotland, and usually less in England; and another "end" is proceeded with, until the agreed upon number of points to win the rink—twenty-one in most English clubs—are registered to the credit of one player or set of partners.

Bosses are smaller editions of quoits, thrown from a shorter distance than the heavier rings of flattened steel used in the more general game. The object of the competing throwers is to obtain a "ringer," flat-side down, over the iron pin aimed at, which is generally fixed perpendicularly in a quadrangular frame or box of moist clay. "Ringers," or the nearest approximation thereto, score towards the agreed-upon number to make "game"; and two, four, or more (rarely) may participate.

Caber Tossing the. This is a difficult feat, performed at the "Highland games" or "gatherings" of Braemar or elsewhere. A stalwart young pine or fir, stripped of its branches, has to be reared, balanced, and flung as far off as possible, lighting fairly on its thicker end, and falling away from the "tossers." A run, with the caber kept perpendicular, is permitted, within bounds, to obtain impetus, and "knack," in addition to preponderating physical force, is requisite in the athlete who would excel.

Canoeing, when one has mastered the art of paddling, is pleasant on placid waters; but it lacks the excellence, as an exercise, of rowing, in that the arms are brought across the body, tending to continuous chest contraction, in proper paddle-manipulation. Less exertion, however is called for in canoeing than in rowing.

Catching the Third is a merry outdoor game in which both sexes may engage. A double row or ring

of participants is formed on the greensward, the couples standing a pace apart in pairs. A would-be catcher stands out in front of the line, or in the middle of the ring, and the foremost of one couple vacates his place, then running to secure a stand before some other pair, the back person of which must endeavour to gain a place in front of the one left alone. The "catcher" may capture any "third" player of a group where two only should be, or any one on the move; when the victim has to become the prisoner and in his or her turn seek to "catch the third."

Coursing has come to be the accepted appellation of the "sport" of racing after, over chosen or prepared ground, and killing hares with running-dogs, chiefly of the greyhound variety. It is intrinsically inferior to actual hare-hunting with harriers, but coursing meetings bring about large assemblies in some places, and they have the advantage over fox-hunting and horse-racing of not requiring equestrian equipment. Greyhounds, in coursing, are guided by sight, not scent; and some "cock" dogs—winners of such trophies as the Waterloo Cup—realise large sums of money.

Cricket of the spectacular sort, in which the picked players—professional and amateur—of the English counties, contend together, or against Colonial combinations, has risen to a great height of popular favour; but the game continues to furnish beautiful pastime to myriads of young men and youths less conspicuously banded together in local clubs. It is played under elaborate rules, approved by the Marylebone Cricket Club, the acknowledged governing body of the game, between teams consisting usually of eleven players aside, upon smoothly-mown and well-rolled turf pitches. The wickets are two sets of three stumps, eight inches wide when in position, topped by two bails laid in grooves, so as to meet end to end on the centre stump, and not to project more than half an inch above the stumps, standing perpendicularly twenty-seven inches out of the ground. These are fixed opposite and parallel at a distance of twenty-two yards. The side winning the toss has first choice of innings; and each of its eleven batsmen—two at once defending, in alternate overs (should run-making not have changed their position), go to the crease, wielding a bat not wider than four and a quarter inches in the blade, nor longer than thirty-eight inches, handle and all. The bat blade is generally of choice willow, its handle of cane, often having strips of rubber compressed under its tight, even wrapping of twine to give "spring" to it. The opposing eleven are placed in the field in positions to prevent the scoring of runs from strokes of the bat or to secure "catches." The ball used in matches is a beautifully made sphere, leather-covered and filled with compressed cork or similar suitable hard material; it must not weigh less than five and a half ounces, nor more than five and three-quarter ounces, and must have a circumference between nine and nine and a quarter inches. A bowler bowls an over of six successive balls to the opposite wicket; then another bowler, at the other end, does the same. The object of attack is to hit and break the batsman's wicket with the ball by removing one or both bails, in despite of his attempts to defend it, or to cause him to strike the delivered ball into the hands of one of the fieldsmen before it shall have reached the ground, in either of which cases the striker's innings is ended. He must keep his foot within prescribed ground whilst the ball is in play, or he may be "stumped" out by the wicket-keeper or "run out" by any of the opposing fieldsmen. For every time the striking batsman, after making his stroke, is enabled to run from wicket to wicket before the ball is returned by a fieldsmen to the bowler, or wicket-keeper, he scores one run for himself and towards the total of his side. Usually four runs are allowed, without any running, for a ball reaching the boundary, and generally six for one driven clear out of the ground. When ten wickets have fallen the innings is over, and the side which has been fielding goes in to bat. In single day matches the issue may be decided upon the result of an innings completed on either side; but in the important games of lengthier duration, two innings by each team are played, unless victory be

previously achieved by one of the sides having registered more runs than the opposing eleven shall have secured in its completed double effort. Any of the attacking side may bowl either fast, medium or slow, left or right hand, and change from end to end to do so, providing always that no bowler send down two overs consecutively in any one innings. Should no definite result be arrived at, through climatic interruptions of play, or the inability of one side to dismiss their rivals before the winning advantage shall have been secured, "a drawn game" is the result. Umpires, one at each end, preside over every properly-played match, and their decisions must be obeyed in all points.

Cricket Ball, Throwing the. As an exercise as well as a means of acquiring proficiency in fielding, throwing the cricket ball is commendable. It is a good deal practised at the schools and the Universities. The longest recorded "throw" is that of R. Percival, on the Durham Sands racecourse, in 1884, over a measured distance of 140 yards and a few feet. "King Billy," an aboriginal professional, had thrown a cricket ball in Queensland 140 yards a dozen years earlier.

Croquet is a favourite lawn game, especially with ladies. It is played on level grass with wooden balls, light hammer-headed wooden mallets, and a series of iron hoops, six or more in number, arranged in a plan on the turf, the space occupied being ten square yards or more. Rules for playing croquet vary, as do the number of persons taking part in the game; and settings are indicated in the regulations supplied by the manufacturers of the requisites.

Cross-Country Running, where courses can be secured, is a capital form of pedestrian exercise for the active; and affords good and healthful practice for many athletic games requiring "condition" and endurance.

Curling is a winter game said to have been introduced into Scotland by Flemish immigrants about the beginning of the sixteenth century. Therein contending parties slide heavy, hard, smooth, round stones about nine inches in diameter, weighing forty pounds or more, with an iron handle at the top, and flattened at the bottom, over well-sept ice towards a tee or mark, forty-two yards, or some other agreed-upon distance, from the curling tee. The objects of the player are to propel his curling-stone fairly to a lay as near to the mark as possible, to guard that of his partner which has been well-laid already, or to strike away that of an antagonist. The number of "points" to make game are a matter of mutual arrangement.

Cycling, as a machine suited in size and fitness to the rider, and properly geared to obviate undue exertion, is a very good medium for the promotion of recreative pastime in either sex. The safety bicycle, well built, can be controlled with a little persistent practice; after that let moderation be the rider's guide. Time should be allowed, in the country "spin," to take in the beauties of the landscape, and no over-fatiguing journey be essayed. Also let the cyclist walk up his machine, as any stiff leg or many riders insensibly inflict injury upon themselves by disdaining this precaution. It is a great mistake to turn invigorating exercise into an exacting task. The warning applies to all pastimes involving sustained exertion. Competitive cycling should for safety and the public convenience be confined to the track.

Dab and Trigger is a ball game indulged in in some localities. The requisites are a wedge-shaped little block of wood, slightly cupped on the upper surface towards the extremity opposite to that undercut, to hold in position a hard and roughened ball of tough wood, about one and three-quarters of an inch in diameter; and a flexible cane, headed with a firmly secured cube of unspittable wood. The player, with this, smartly "dabs" the trigger end of the block on the ground, causing the ball to spring from its resting place into the air, and with a deft swinging drive seeks to strike it as long a distance as possible.

Deer-Stalking is a sport of the rich, involving the up-keep of the forest land which yearly becomes more and more limited. Only a few fastnesses affording sufficient cover for the "antlered monarch of the glen"

remain in Britain. Civilisation circumscribes "blood sports" by largely extinguishing the avocation of the hunter, and incidentally rendering communities habitually humane. Latter-day strenuousness in the great game of life has made the chase unfashionable with the million, and to hunt or stalk the stag you must now first preserve him, a costly process.

Diabolo. This game is played with two sticks, each about two feet long, with each end of a piece of cord about four feet long joined to one end of both sticks. The "diabolo" consists of a piece of wood or other suitable substance in the form of an egg-boller or two peg-tops joined at the pegs. The player holds one

should never be practised, even by an adept, except in known waters.

Egg and Spoon Racing is a simple diversion where children and people of mixed ages are to be amused. Steadiness of hand, fleetness of foot, and some practice will make a winner. A flattish wooden spoon, an egg, and any number of entrants are wanted for the game; the object being to cover the greatest distance in the quickest time over the grass, with the egg maintained in position at arm's length.

Egg Hat is the throwing of a ball—a bouncing ball preferably—into several hats in succession from a given distance; the player bringing the ball to rest in the

Diagram of Ground as marked out for Croquet.

stick in each hand, suspending the diabolo on the string, and by holding one end of the string higher than the other, the diabolo is made to spin down the string, and to and fro by alternate elevations of each hand. By repeating this action several times rapidly, the diabolo gets on to a quick spinning motion, when the string is suddenly tightened by bringing the ends of the stick wide apart, which has the effect of making the diabolo spring into the air. As it descends it is caught on the tightened cord, when the spinning process is again gone through, and the diabolo again thrown into the air. The object is to see how quickly and how high the diabolo can be thrown and caught without letting it drop to the ground.

Diving is a part of the swimmer's accomplishment, and one that is very desirable. It is a branch of the nautical art which must be mastered gradually, and

greatest number of hats with the smallest number of clean casts winning the contest.

Falconry was a favourite field-sport in Britain in the Middle Ages, as elsewhere, by the nobility and landed gentry, who made it a serious business of their lives; but what few herons there are left in these isles—as well as other fowl whose progenitors were the prey of the trained hawk, and the sport of its owners in former times—now enjoy immunity from organised pursuit, and falcon-hoods, jesses, bells, and tassels, belong to our past history.

Feeder was a ball-game, very much akin to "rounders," engaged in by three players. The feeder with a light ball "fed" the other two in succession as batsmen until he could put one of them out by a catch in the air or by hitting him with the ball whilst running between bases after a stroke. The feeder took his

stand centrally between the bases, and if the striker could get round before the third player left the home base to run, he took strike again. Meanwhile he was safe, when on either of the three out bases, so long as he could elude the touch of the ball from the feeder. If the latter recovered the stricken ball before either of the batsmen got home, and therewith touched the home base, both were out. The striker first "outed" took the feeder's place, and when an agreed upon number of innings had been played, he who had run round the bases oftentimes from strokes of his own was proclaimed the winner. The ball was pitched and struck in the air, a very light bat or rounded stick being employed.

Field Hockey. (See *Hockey*.)

Field Sports. (See separate entries in this sec-

side first scoring fifteen wins. Fives is an ancient game, called in Scotland cage or catch-ball, and in France palm-play. A fives-court is provided at many schools. Light bats are used in some places wherewith to strike the ball, in a variation of the game.

Football, Association. This development of the old English and Scottish game of ball is played between two sides of eleven men each, on a quadrangular field, not less (in International matches) than one hundred and ten yards or more than one hundred and twenty yards long, and between seventy and eighty yards wide. Parallel lines, marked out by flags at the sides of the playing area, are "the touch" lines; and those at the ends, at right angles to the former, are the goal-lines. In the centre of these, facing each

tion: **Archery, Cricket, Croquet, Football, Hockey, La Crosse, Polo, Shooting, etc.**

Fishing. (See *Angling*, and *Sea Fishing*.)

Fives, played in an out-door court, is a species of hand-tennis, in which a soft ball, covered with thin leather, is struck against a wall by the palms of the hands of the players, usually two or four aside. The leader of the serving-side bounces the ball on the ground and strikes it, on the bound, at the wall, anywhere above a horizontal line marked at a height of three feet, to rebound over a ground line parallel with and six feet from the wall. The players, ranged alternately outside the ground line, have to strike back the ball on the further rebound, either before it reaches the ground or at the first bounce. Should one of the serving-side fail to strike the ball back to the wall properly, or strike it so hard that it bounces out of bounds, the innings of the side is lost. If one of the out-side should miss or strike the ball ineffectively, a point is counted to the score of the serving-side. The

other, are fixed the goals, consisting of two upright posts eight yards apart, with a cross-bar eight feet from the ground, and having a net loosely placed at the back to catch the ball and ensure its having gone between the posts. A half-way line is drawn from side to side of the field, parallel to and equidistant from the goal lines. The ball, a round leather-covered bladder (which must, in important matches, measure between twenty-seven and twenty-eight inches in circumference) is kicked off from the centre at the commencement of the game. It is for each side to prevent the opposing eleven from getting the ball into the net, between the posts and under the cross-bar of the goal it has to defend; and, what is even more important, to strive to get it by pass or direct kicking, or heading, into the antagonists' goal. In all this strenuous endeavour the ball must not be intentionally handled by any of the players except the goal-keepers, in catching and clearing from the goal under their custody. Even then players may not carry the ball more than three paces

without relinquishing it. No player is permitted to hold or push an opponent with his hands, and tripping, jumping at, or kicking an antagonist are alike illegal, and a free kick is awarded against the offenders from the spot where the offence took place. When forty-five minutes' play is completed, the referee blows his whistle, and the game stops, "half-time" having been reached. After five minutes' interval the game recommences, the sides changing ends; and the eleven having registered most goals, in both "halves," after the full ninety minutes' play, is the winner; should there be no score on either side or an equal number be obtained, the game is "a draw." When a goal is scored, the side at whose expense it has been made kicks off anew from the centre. There are explicit

plonships, and International matches attract thousands of eager spectators.

Football, Rugby. Rugby football, in which the ball is of oval shape, and which is played fifteen aside, differs mainly from "Soccer" in the participants being permitted to take up the ball whenever it is bounding or rolling, and run with it towards the goal. The player, carrying or holding the ball, must, however, immediately on being tackled or held by an opponent, throw the ball towards his own goal to one of his own team to continue the run, and a goal can only be obtained by kicking the ball from the field of play direct over the cross-bar between the side posts of the goal. In the Rugby Union game the uprights of the goal are placed 18 feet 6 inches apart, and must be made

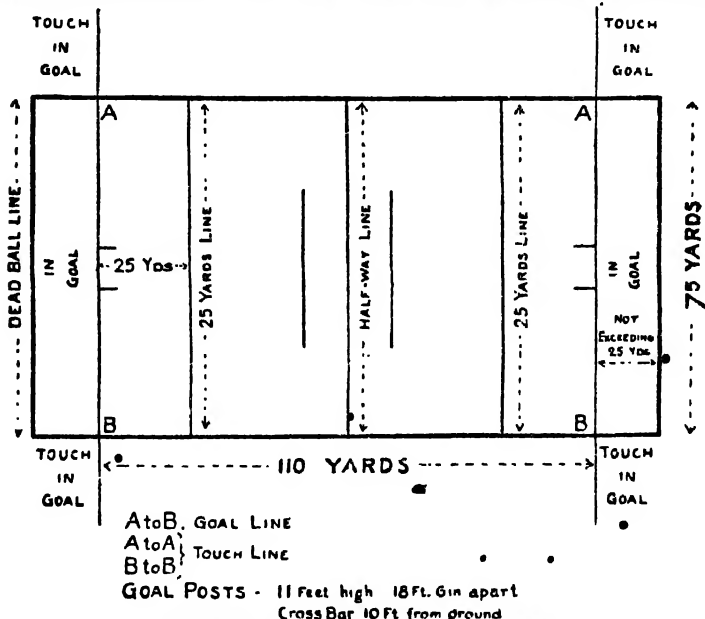

Diagram of Ground as marked out for Rugby Football.

rules governing the procedure when the ball has been kicked into touch or over the goal-line, in both of which cases it is out of play whether the line be crossed in the air or on the ground, and also as to the permissible positions of the players during the game, with regard to the positions occupied at any given juncture by members of their own and the opposing teams. Penalties are imposed for "off-side" and other infringements, and these the referee, who is assisted by two linesmen, has to enforce. Usually an eleven of "Soccer" players consists of five forwards (outside right, inside right, centre, inside left, and outside left); three half-backs (right-half, centre-half, and left-half); two full backs (right-back and left-back), and one goal-keeper, all chosen for their special proven ability in the positions to which they are allocated; and the men are expected to work in harmonious combination. Association football, which is seasonable in England from September till the end of April, is a very fascinating winter game; and the Cup Ties, League Cham-

11 feet in height, the crossbar being fixed 10 feet from, and parallel with, the ground. The ball weighs (in important matches) between 13 ounces and 14 ounces, with a circumference lengthwise of between 30 and 31 inches, and a width-girth of from 25 inches to 30 inches, while the field of play must approximate as closely as possible to 110 yards long and 75 yards in breadth. The "scrum," or scrummage, is an important feature of present day Rugby football, and is caused as the result of a foul against a player or other reason. It is formed by the eight "forwards" on each side facing each other with lowered heads. Three in the front rank, two in the second rank, and again three in the last rank. The ball is then thrown in by the "half-back" between the two front ranks; the opposing forwards strive for the possession of the ball by "hooking" it with their feet, i.e., driving it to the man behind (this applies only when outside the home 25), who "works" the "scrum" for further kicking and open play. In the game, as played under

the Rugby Union rules, a try (gained by a player who first puts his hand on the ball on the ground in his opponents' in-goal) counts three points for his side towards game; a penalty goal (there are numerous penalties—for which free-kicks are given—arising from infringements of the governing laws) equals three points; a goal from a try reckons five points (in which case the try from which it resulted does not count); and any other goal is worth four points. The side with most points, thus calculated, at the close, wins the game. In the Northern Union game the value of points is differently assessed. In the United States, football is played by eleven men aside, kicking and running with the ball being both legal, and the scoring is for goal (kicked over the 10-foot high crossbar and between the uprights) from the field of play five points; for touch-down (when the ball is carried and touched-down to the ground behind the goal line), five points; for a safety-touch (when an opponent has been compelled to carry the ball and touch-down behind his own goal line), two points; and, for a goal kicked from a touch-down, six points. The game occupies two thirty-five minutes' halves, and the ground is marked out with white lines five yards apart, as the ball must be surrendered if not advanced that distance in three running attempts on the part of members of an American side. In the United States the regulations for the great football matches are most intricate. All these developments, of what is classed as Rugby football have grown out of the "Big Side" game so favoured last century by the boys of the great English Midland School (which can itself be traced back to a Continental origination). They comprise various combinations of football, handball, "tackling" and pushing in unison, calling for the exercise of much physical strength, agility, courage, and scientific resourcefulness of movement, both as regards the individual efforts of the players and the organised and harmonious action of wings, sections, and the entire opposing teams.

Fox-hunting is the most extensively patronised survival of the chase, as a "blood sport," so far as England is concerned. The quarry has to be carefully preserved in well-guarded coverts, and the hunting (seasonable from the beginning of October to Lady Day; cub hunting, August 1st to the first Monday in November) requires the upkeep of a pack of hounds for each district, a huntsman, whippers-in, kennel-keepers, and helps; as well as suitable horses, bred for fence and water-jumping and running across country, for the masters of hounds and the ladies and gentlemen of the hunt in each allotted district to ride. The sport is picturesque, exhilarating, and accompanied with its spice of danger, especially to hard and reckless riders; but it is regarded as characteristically English and eminently aristocratic.

Golf, some say, is a game of the leisure or middle age; but it is indulged in with increasing zest by persons irrespective of age, sex, or rank. The pleasure of a three-mile walk over well-kept, breezily-situated "links," and the fascination of driving, putting, and all else belonging to the golf game—which had great vogue in Scotland before its hold upon England became extensive—possesses a charm for many statesmen and persons ordinarily engaged in exacting professional pursuits. Golf is played with quite a number of implements nowadays, carried by an attendant caddie. These are club-headed sticks or irons, called drivers, bulgers, niblicks, putters, spoons, mashies, brasses, corks, mallets, lofers, etc., and small, hard, white resilient balls, made of gutta-percha, or with special rubber cores. On large downs, commons, or specially preserved courses, often by the seashore, the "links" being elaborately laid out with interposed impediments, natural or adapted, in the way of hollows, banks, mounds, and even trees. The object is to strike or "put"—in the fewest possible strokes—the ball, with one or other of the clubs, into each of eighteen (in a full course) small holes, about 4 inches in diameter, cut in the turf on specially prepared greens. The holes may be as close as 100 yards from the "Tee" or any thing between 300 and 600 yards off, and their position is usually marked by flags. At the start for each ordinary hole the ball is "teed"

on the summit of a little heap of sand or soil, and therefrom propelled, by one stroke of the driver, or other selected club, with all the force and judgment at the striker's command, to a position as nearly as possible to the objective hole. A full "drive" including the length of the flight of the ball in the air and the distance it will thereafter bounce and finally roll along before coming to a standstill, from a powerful stroke by a practised golfer, is about 200 yards, and even more. And then another stroke is made which varies according to the distance to the hole. Some holes are short, and require a skillfully-hit ball to land it in one stroke on the "Green." When the ball comes to rest behind a "bunker," or in long grass, and has therefore to be got to the hole, the special club devised for the purpose has to be skillfully employed. The most accomplished golfers have, at their best, managed to "hole" the ball in all the eighteen holes with an average of less than four strokes per hole in a very exceptionally good round; and in the championships, four rounds of a course are played. Matches are either "singles" between two opponents, or "foursomes," in which a quartette of players engage, two on each side playing alternately with the same ball. One must know the "links" well, and be able to judge distances and gauge wind-force and rely on one's own play to get the best attainable results in a golfing competition; but, fondness for the game having once been acquired, it certainly furnishes a healthful and not too exacting outdoor relaxation, usually with very agreeable surroundings. Each player (or pair of players) uses a separate ball.

Hare and Hounds. This is an organised system of Cross-Country Running (*qv*), in which clubs or schools engage for exercise in the winter time; a fleet-footed participant (or, in cases, two in company) being dispatched ahead of the rest, who form the pack. Not only do the "hares" set the "hounds" as fast a pace as they can, but they endeavour to elude pursuit by legitimate doubling and dodging; and by taking any available cover, after having put the pack off scent by leaving behind them a cunningly crossed trail. When the hiding-place of the hares is discovered, they will break away for a further run. In suitable country—with plenty of upland and hollow, as well as copse, to elude pursued and pursuers out of each other's sight sufficiently often to render the sport interesting, and also with a good show of stiff hedges and wide ditches to negotiate—"Hare and Hounds" is fine fun for strong-winded lads.

Harriers are packs of hounds, resembling, but somewhat smaller than, foxhounds, used for hunting hares by scent. The larger harriers are somewhat slow-moving, but the smaller fox-beagle is alert and lively. In the chase, the hare, being found in the form, is allowed a little "law" before the harriers are loosed after her, and must not be pressed upon by the huntsmen, who follow on foot. Neither is it usual for the dogs, should they lose scent, to be directed to the course of the quarry, but they are left to discover the right track by themselves. The sport is one greatly esteemed by many, as affording exercise and excitement, and being legitimate hunting, the "bag" furnishing excellent eating. Hare-hunting, carried out under proper arrangement, possesses great attraction.

Hawking. (See *Falconry*.)

Highland Games. Scottish gatherings at which athletic sports, wrestling, foot-dancing, tossing caber, and other exercises are indulged in.

Hockey is a game of ball played with sticks or clubs having hooked or curved ends, and is popular with both sexes, as providing admirable exercise for arms and legs alike. It is played, under well-devised rules, between a number of persons in parties or sides, the object of each team being to drive the ball, by individual and combined skill and dexterity, assisted by fleet running, through the adversaries' goal. The defence seeks to frustrate the attack, and *vice versa*. The ball is small and of hard rubber, and hockey is played on ground marked very much as for football, the general method of the two games not being dissimilar, though of course the ball has at hockey always to be struck with the stick, and never kicked or

carried. In Scotland a variation of the game is called "shinty," in Ireland another adaptation is known as "hurling." Hockey is sometimes in winter played by skaters on the ice.

Hoop-Trundling will always retain popularity as a pastime in which boys or girls may obtain running exercise singly, or in couples or groups, in contention for speed and the longest possible maintenance of the hoop in the forward-bounding perpendicular position. The large hoop of light, pliant wood, and the straight stick for driving are most favoured by female trundlers; lads like the hoop of iron and a propeller of hooked metal with wooden handle.

Hop-Scotch is a juvenile diversion consisting of the kicking with the toe of one foot—keeping the other off the ground—of a flat stone out of and into understood positions on a geometrical diagram chalked upon flat pavement, varied as to definition in different localities, but always giving scope for agility.

Hop, Skip, and Jump is a combined triple forward movement of the character indicated by its

participated; and though the ball might never be handled, it could be carried forward on the "hurley" as far as possible, and any amount of tackling and wrestling seems to have been admissible on the part of the players to get their antagonists "off the ball." It was, in its heyday, a very strenuous sport, in which many hard knocks—not always unintentional, it is to be feared—were given; but the fun was characteristically Hibernian. In the beginning the opposing sides lined up "with crossed hurleys" in the middle of the field of play, when the ball was thrown straight into the air to fall in the midst of the players, each team immediately thereafter concentrating its efforts upon getting it into the goal which it was the business of the other side to defend. The scorers of the most goals, of course, won the game.

Ice Hockey is a pastime very much indulged in in Canada, and at times in other places where and when natural ice or an artificial rink may be available, the players being usually mounted on bladed or roller skates. The difficulty of keeping a balance in such

name, usually preceded by a run to the hopping-off base, the endeavour being to cover the longest distance possible to the competitor in the separate and full number of steps. At sports in the North of England room is often found for a contest of this simple kind.

Horse Racing, which engages the attention of so many thousands of people, both rich and poor, in all parts of the world, is not a sport which comes within the compass of present treatment. It is the business of a class, and the spectacular attraction, for social or gambling reasons, of a multitude of all ranks.

Hunting. (See *Beagles, Deer-Stalking, Harriers, Otter Hunting, Stag Hunting*, etc.)

Hurdles. The leaping over hurdles, usually of graduated height and "stiffness" as to "taking-off" and landing, either in a foot or equestrian steeplechase, or singly in competitions at school or other sports. Speed and the clean-clearing of the interposed obstacles are the object.

Hurling is the Irish variety of hockey, similarly played, by an equal number of antagonists, with crooked sticks and a ball to be struck into opposite goals. As many as sixty or even more players have

conditions adds great zest to the game as ordinarily practiced.

Ice Polo. Polo, played on ice, is a pastime highly spiced with danger, needing courage and much practice on the part of those engaging therein.

Indian Ball Game was a diversion in which the North American Indians were very expert, using two netted sticks or bats to strike a ball beyond certain bounds, the while opposing players endeavoured to force it in a contrary direction. It originated the Canadian national game of *La Crosse*, *q.v.*

Jiu-Jitsu, is a Japanese method of wrestling, involving a severely scientific physical training. The term literally means "muscle breaking." The wrestler endeavours to get a tight grasp with his left hand upon the left wrist of his adversary, both wrestlers being erect, and lever him backwards, administering a throat blow with the flat of the right wrist, which generally proves a "knock-out." The Japanese attach much more importance to the development of the muscles in the region of the elbow than those of the upper arm; and their jiu-jitsu system, which implies all-round physical training of a highly intelligent order, renders them most difficult to overcome in single combat without weapons.

Jumping is an individual natural exercise to perfection in which practice is essential. As to what thereby can be achieved it may be noted that an Irish amateur, Mr. P. J. O'Connor, cleared in 1907 with a running long (or broad) jump at Kilkenny a distance of 24 feet 11 inches; and Mr. Ray C. Ewry in America 11 feet 3 inches in a standing long jump. Mr. M. Sweeney cleared in 1895, in a running high jump (in America) 6 feet 5½ inches, and Mr. P. Leahy (in England) 6 feet 4½ inches; while Ray C. Ewry got over a string 5 feet 5½ inches high at a standing high jump in America in 1901. In Inter-Varsity contests in England, Mr. C. B. Fry for Oxford in 1899 broke previous records with a long-jump of 23 feet 5 inches, and Mr. M. J. Brooks (also a Dark Blue) got over a 6 feet 2½ inches line at the 1896 sports in a high jump.

Kiss in the Ring is a social diversion in which the players must be on sufficiently intimate terms to render familiarity inoffensive. Then, engaged in with spirit and good temper, it furnishes fine fun in the open, especially to the young of either sex. One player stands in the centre of a ring formed by the rest.

As widely as possible in formation. Sometimes the game is played to the accompaniment of a play-song, in which the isolated participant is enjoined, vocally and musically, to "close the pretty girl," he "likes best." This done, he advances and touches one of the ring, who must then break away from the hands she has been holding—the ring immediately closing up—and run under the arms of the other players, "in and out and round about," to avoid capture, and if she can—and desires so to do—before being held, regain a position as part of the ring by breaking the hold of the players and taking a hind of each, thus reforming the circle. Then the pursuer must commence all over again. But if she is caught, she is led triumphantly into the centre of the ring and kissed. Immediately thereafter, her captor joins the circle, and she becomes in turn chaser and pursued, with renewed singing and merriment. Sometimes the chosen is, perhaps after giving a good run for the fun of it, an easy capture. That depends upon who the pursuer may be. But affability and an even distribution of the sexes are essential to the success and the charm of the simple old pastime, which is a survival of the old English May Games, themselves an adaptation of amusements of far more ancient date.

Kite-Flying as a pastime for the young, was introduced about the end of the 17th century into Britain from China, where persons of mature years still engage in it. The kite is usually formed of paper or a thin textile fabric, pasted on a flat frame of light wood and cane, with balancing tail and tassel wings; but various fanciful shapes are employed, considerable skill being necessary for their proper construction and management in the air at the end of a slender string. The secret of the right way to attach the string is a fitted "belly-band" on the frame near the centre of gravity, and keep the flat surface in oblique presentation to the wind.

Knur and Spell. This is a variety of the game of "trap, bat, and ball," having affinity to "dash and trigger," already noticed; the light ball being struck away when released in the air from a simple trap. It is called in some places "Nurr and Spell," in others "Northern Spell," which latter term is probably the more correct, as indicating a northern adaptation of an old and simple game. It is played for prizes in the manufacturing and colliery districts of Yorkshire, Lancashire, and neighbouring counties by the working classes, adult as well as juvenile.

La Crosse, a development of the Indian "ball game," nationalised in Canada, and localised elsewhere, is played by sides as at football and hockey, with sticks four to five feet long, bent at the end like a bishop's crozier, and netted in tight-drawn gut to a point more than half way down the shaft. The ball, of hard rubber, may be driven with, or carried on the crosse towards goal, which consists of a couple of posts seven feet apart and a transverse bar six feet high. The play space is divided into two halves, of dimensions similar to those obtaining in football, each half being in turn defended by the opposing sides.

Lawn Billiards. This game, also called "Troco," is played on well-mown and rolled turf, as level laid as possible. An iron ring is fixed in the centre of the ground, and the players—two or more in number—are provided with cues, iron hoops at the end. The object is to drive the ball through the ring with a forward stroke, which counts one towards game; or, first striking your opponent's ball, to get your own from the impact under the ring, which is a cannon, and counts two; or, to drive your antagonist's ball through the ring, counting one. The "break" continues until the player fails to score, when his adversary strikes. Eleven, fifteen, or twenty-one may make game, the larger number being usually agreed upon when there are sides instead of single players.

Lawn Tennis is an enjoyable out-door game, played over a net on close-cropped grass, as for "Badminton," with light broad rackets and balls of white felt-covered rubber, instead of a shuttlecock. "Courts" of regulation dimensions are marked with tape or whitewash. The "server" serves across the net diagonally to the opposite court; "striker-out" returns, until one fails, and yields a point. Either player loses a point if the ball in play strikes his hand or any part of his person, or if the ball be struck twice. "Striker-out" becomes "server" at the end of a game. According to the laws of the All England Lawn Tennis Club "on either player winning his first stroke, the score is called fifteen for that player; on either player winning his second stroke, the score is called thirty for that player; on either player winning his third stroke, the score is called forty for that player; and the fourth stroke won by either player is scored game for that player. Except as below: If both parties have won three strokes the score is called deuce; and the next stroke won by either player is scored advantage for that player. If the same player win the next stroke, he wins the game; if he lose the next stroke the score is again called deuce, and so on until either player win the two strokes immediately following the score of deuce, when the game is scored for that player." In the four-handed game the players take the service alternately throughout each game. The rule is that no player shall receive or return a service delivered to his or her partner. The order of service and of striking-out once arranged must not be altered, nor shall the strikers-out change courts to receive the service until the end of the game." The side first winning six games wins the set; except when both sides have won five games, when the score is called games all. Then the next game won by either side is called advantage to the winners, who, should they win the next game, take the set. But, should they lose the next game, the score becomes again games all; and so on until either side win two successive games and the set. Usually a lady and gentleman are partners in the four-handed game, which is deservedly popular to both sexes in the summer time. Clubs play it with very strict regard to code governing the service-line, half court-line, side lines of courts, "volleying," the positions of the players, the method of service, and the definition of "faults."

Leap Frog is a boys' game, in which the *modus operandi* is "the giving of a back" by one lad and the leaping thereover by another, the leaper touching the crouching player's back and getting an impetus forward, legs astraddle, to alight and recover in the erect position at the greatest possible distance. He of the two who gets furthest forward cleanly wins. The croucher has to stand as firmly as he can, his body parallel with the ground, and his head bent downwards, or he will be enjoined to "tuck in his twopenny." The leaper is allowed a run before "taking off" at a fixed distance from the back he has to clear, which may be high or low, according to physical possibilities, so long as rigidity is maintained. North-country lads call this sport "loup back" (leap back).

Marbles. Boys play a variety of games with small spheres, often of stone and glass, but of marble, plain or coloured. These are assessed at different values for play, the staple being the "alley-tors," or taws, worth three (usually) of the "commoners" or "bouldies." The "blood-alley" or "Dutch alley," of

prettily-marked, red-veined, hard, tough marble, procured from quarries near Coburg, in Saxony, is a particular favourite with many lads; the gorgeous elliptically-ringed "allies" of glass are too brittle for the knocking-about they would receive in the games of "shot" and "ring-taw" in which boys delight. Other games with marbles are hand, hole, and odd or even, the principle being by good aiming to get the marbles into a small hole from a given distance; to strike by a finger and thumb shot your opponent's marble, placed on a mark, with your own; or to drive out and capture marbles by alternate approaches from a ring in which they have been stakes, each player getting all he fairly can. Many ingenious games, combinations of shooting and bowling the marbles, are known to most schoolboys. The marbles employed by the players are stakes in the games, and experts in luck are continually "skinning" out their less fortunate antagonists, who have to replenish their stocks by purchase. A variety of marble play in which one boy owns a wooden frame, serrated with small piercings at intervals, is popular in some parts. Over the holes are

and license, and in London in Bluff King Hal's time this lawlessness culminated in the excesses of *Evil May Day* (1517), when the rioting of the city apprentices, in resentment of alien immigration, had to be suppressed by the soldiery, and was followed by the imprisonment of some three hundred of the mob, and the gibbeting of several. This, and a later ebullition of Puritanical animosity against all manner of joyful demonstrativeness, killed "Maying" as an institution in Britain, and banished the Maypole as a "long wooden idol" from the land. But the spirit from which sprang the "May Games" and the "Whitsun Ales" of our forefathers survives in the many popular holidays and gala gatherings that still—with far fuller facilities—mark the spring and early summer on the various recreation grounds.

Mass Running is a lively exercise, forming part of the curriculum of physical drill in some of the schools, varied in character, and calling for no special description.

Medicine Ball is the passing from hand to hand of a heavy ball, a species of exercise favoured much in

Diagram of Ground as marked out for Lawn Tennis.

numbers, say from one to nine, a low number being placed next to a higher one. The frame is placed on the pavement as the playground, the players roll from a stated distance their marbles towards the holes. The stake is the bowled "boudy." If it fails to enter any hole it becomes forfeit to the owner of the frame; should it enter it wins for the bowler as many "boudies" as are marked over the hole it went through. The frame-owner, having a good reserve stock to pay out with when the bowlers are in luck, usually has the best of it in the end, like the keepers of the bank in gambling games of greater import.

Maying and May Games were merry gatherings of the populace in the open in olden England, derived in a measure from the *Floralia* feasting of ancient Rome, in celebration of the resumption of the reign of the goddess of the flowers. There were archery, morrice dancing, and other devices for pastime all day long, and bonfires, stage-plays, and all manner of hilarity in the streets at night, presided over by the Lord and Lady of the May. The rich in authority provided the wherewithal for the entertainment of the multitude; but the free fun degenerated into disorder

American outdoor gymnasium. The ball weighs from four to nine pounds, and the catching of it strengthens the muscles of the back, legs, and arms, develops the chest, and invigorates the system generally, whilst affording very considerable amusement.

Model Yacht Sailing is a pastime possessing singular charm for many, and affording scope for the exercise of constructive skill, and ability in the management of the tiny craft upon ornamental waters in the parks and elsewhere, especially on breezy days.

Morrice Dancing. Morris or Morrice Dancing had great vogue in medieval Britain as an open-air diversion, the performers being fantastically attired and assisted in their gambols by the noise of the castanets and rattles which they manipulated. It was of Moorish derivation, and was probably brought from Spain, *temp.* Edward III., by John of Gaunt; holding high favour until about the reign of Henry VII., and finally thereafter.

Nicholses, obsolete now, was a game in which a number of holes, according to the number of players, were made in the ground in front of a wall or other barrier, just large enough to receive a ball, which was

bowled from a prescribed distance. "Egg-hat" (*g.v.*) was a variation of the simple pastime.

Northern Spell. (See **Knurr and Spell.**)
Oallone, an adaptation of an old Italian game, "Pallone" (*g.v.*), very similar to rackets or court tennis; quite forgotten now as far as Britain is concerned.

Obstacle Racing, a diversion furnishing occasion for ingenuity on the part of the devisers of outdoor sports, and fun for the spectators, who never merry over the difficulties created for the competitors to overcome or be defeated by. It is a comedy element of summer gatherings which requires here no elucidation.

Otter Hunting. Formerly a common British sport, this can rarely now be indulged in, because of the increasing scarcity of the quarry. Otters would always "put up a good fight" with the hounds trained to hunt them for their riverian seclusion and chase them along the banks of a stream, or follow them when they took the water; but for the assistance of the huntsmen who helped the dogs to harry their quarry, it was generally odds on the otter escaping in his familiar haunts; and in any case he might be expected to maim and drown dogs before being vanquished. Where one of the family of *Lutra vulgaris* survives, he is generally unceremoniously slain as a poacher at the first opportunity.

Pail Mail, the forerunner of croquet, very fashionable in Stuart times. It consisted of the driving with a wooden mallet, in divers directions, of a ball through hoops suspended from poles or driven into the ground, or both; and was often played by ladies and gentlemen on horseback. The sport originated in France and was there called *Paille-maille*. It was played in the park of St. James's Park, London, as a good deal; and the name of the game is perpetuated in a famous adjacent street.

Pallone. This—corruptions of which have travelled westward, one having for a while some favour under the name of "Oallone" (*g.v.*)—is the national ball-game of Italy, dating back to Imperial Roman times, and flourishing exceedingly in the great days of Florence. It is a kind of croquet, between tennis, as we know it, and football, the wrist, however, armed with a bracelet, being employed in striking the sphere. Pallone holds its own as a popular pastime in Italy, and is played with much ceremony, and under strict regulations.

Paper-Chasing is a "conditioning" exercise favoured in boys' schools, especially in cold weather; a species of cross-country running, in which "scent" is laid in a trail, with fragments of paper or confetti, by lads allowed a start of their pursuers. (See also **Hare and Hounds.**)

Palota is a Spanish wall and ball game, usually played by sides and three against three, in an open court with a *fronton* on, or back wall for the rebound, and a rectangular wall at one end slanting downwards at top from the *fronton*. The players stand twenty-five yards from the *fronton*, and strike the pelota or ball with terrific force against the wall, higher than a mark a yard from the ground, using a "chistera," or strong hollow-curved basket, about 3 ft. long, and strapped to the arm. The server sends the hard ball like a cannon shot to the *fronton*, and on the rebound the other players in succession volley it along until a fault is made, counting one against the side responsible. Save for the use of "chistera" and the amazing velocity of the "palota" the game and its regulations resemble "fives" or wall tennis.

Pole-Jumping. Pole-jumping, leaping or vaulting is the increase of the height-clearing power of the leaper by the use of a pole of a regulated length. At Kildermister in 1861, Mr. R. D. Dickinson jumped 11 feet 9 inches with the aid of a pole; and a pole vault of 11 feet 10 inches has been recorded in the United States.

Polo may be simply described as hockey on horseback. It is played by riders on specially trained ponies, long-handled "sticks," or mallets, being used to strike the ball from the ground towards goal. The game was introduced from the East, and is very popular at gymkhanas and military sports, as it permits the display of much equestrian skill and muscular dexterity, while the danger involved proves an added charm to daring riders. The ball—of white-painted

willow-root—must be light enough not to injure the legs of the ponies. Its diameter is about 4 inches. Under the rules codified by the Hurlingham Club—which govern all match and exhibition games—polo is played by eight players, four aside, each having his appointed place and particular duties in the game, his energies being directed to the dual task of impeding the course of the ball towards his own side's goal, and accelerating its progress in the direction of that of his antagonists. Player No. 4 on either side is the back, a position of the greatest responsibility; he guards his goal, and passes the ball forward to No. 3 of his own side, exerting himself all the while to prevent being "ridden-off" by No. 2 of the opposition team. Good polo is played at full gallop on ponies 14 hands 2 inches high, and the "off-side" and "riding-out" laws are rigorously enforced by the appointed umpires.

Prison Bars, or **Bars**, was an old game, like "rounders" or "feeder" in many points, which once held considerable vogue, and had to be prohibited by proclamation in the reign of Edward III. at Westminster, during the sitting of Parliament, from the inconvenience it caused to passing legislators. The full game was played twelve-aside, and there were inter-country matches at "base" in Britain as late as 1880. Cricket has swept it away in this country; base-ball preserves its name, and some of its cardinal features, in America.

Punting, in aquatics, is the propulsion of a flat-bottomed boat in still waters, by means of a long pole pressed to the bottom. It is a useful and easily acquired accomplishment for fishermen and water-fowl shooters, and an enjoyable form of boating in suitable conditions generally.

Pushball is played with an air-inflated ball 6 feet in diameter, weighing about fifty pounds, by opposing sides eleven in number, the object being to roll the ball to a given place, while the antagonists push in contrary directions. A variation of the game is played on horseback, the rider making his "mount" assist him with his lanchers. This kind of push-ball is exploited occasionally at military sports and tournaments.

Putting the Shot is an athletic exercise demanding considerable skill as well as great strength. Mr. D. Horgan "put" a shot weighing sixteen pounds a distance of 46 feet 53 inches in 1864, according to the British official Amateur Athletic Association record; and this has been slightly surpassed in America.

Putting the Weight. A feat similar to the latter (the weight being square instead of round, but also sixteen pounds avoirdupois) has been accomplished by Mr. Horgan, the athlete already mentioned, in Ireland, his record distance being 48 feet 2 inches in this instance. The square sixteen pound weight was "put" 43 feet 10 inches by Mr. W. W. Coo at the Inter-Varsity Sports of 1862 for Oxford.

Quarterstaff, Playing at. Men-at-arms and retainers amused their long and tedious days by bouts with the quarterstaff, giving and receiving many hard knocks, some kind of gesture rewarding the victor. The weapon was a stout staff usually about 6 feet long, iron-loaded at either end, and was grasped by one hand in the middle and by the other between that and the end. In use the latter hand was rapidly brought from one quarter of the staff to the other, imparting to it a swift circular motion, capable of being directed to the delivery of shrewd knocks at unexpected points upon the staff or person of the adversary. Great dexterity was requisite at quarterstaff play to avoid injury.

Quintain, Running at the. An ancient tilting sport. The quintain consisted of an upright post, over the top of which turned easily upon a pin a stout circular beam. The game was to gallop up and endeavour to strike heavily with extended lance upon the broad end of the beam, sending it swinging, and get out of the way before being smitten with a sand-bag suspended from the opposite end of the revolving quintain-head. To miss the quintain with the blunted lance point was a fault, to strike it and spur away unhit by the bag was dexterous horsemanship. Sometimes swords were used by the tilters in lieu of lances; while for the cross-beam was occasionally substituted a substantial wooden effigy of a soldier fixed on a

swivel, a shield in one extended hand and a heavy sword in the other.

Quoits are used in a game which comes down from the discus-throwing days of the Greeks and Romans. "Hoops" of iron are driven into the ground at a distance of 18 to 25 yards, and the players endeavour to cast over one "hot" steel quoit pitched from the other. These are flattened rings, convex on the upper side, 8½ inches to 9½ inches in diameter, and from 1 to 2 inches wide in the ring; their weight varying from 4 to 5 pounds the pair. The nearest cast to a "ringer" wins the throw; and, to count, the quoit must lie rounded side up. The opponents pitch up a quoit alternately, playing in a single-handed game from end to end in succession; and one of each side from either end in turn at the four-handed game. Usually 15 points is reckoned game when four players participate and 11 when only two are engaged.

Racquets, or Rackets. Usually practised in an open space bounded by a high wall at one end, this game resembles "Fives" in the wall-play. The racquets are netted with stretched gut, the balls very hard and about 1½ inches in diameter. The "in-players" (two or four aside may play) guard the inner courts, the "out-players" outer courts. The "in-

complete control of the mount he or she may be able to command. Persistent practice, in this as in all else, brings about perfection.

Rogue is a lawn game in some sense like lawn-billiards, again resembling croquet at points, and would appear to have been adopted in America from the latter game. Its chief feature is the driving of the ball of your opponent by the impact of your own, after a stroke from a short-handled mallet, and getting either or both balls through a ring, on the stroke.

Rounders (of which *Feeder*, *q.v.*, is a variety) is a game that players of differing ages and sex may engage in and enjoy. There should be at least five players a side. The ball should be light and of moderate size, the "bat" a rounded stick easily wielded with one hand. A player on the in side stands on the home base, stick in hand, to receive the ball with his bat from the pitcher, who faces him at about a dozen yards' distance. If he miss striking the ball, pitched to him in the air, three times successively, he is out, and one of his four fellow players comes in to take strike. On hitting the ball the striker may begin his round of the bases placed diagonally to each other about thirty yards (or less); or he may defer doing so until he has dealt with the third delivery.

Diagram of Ground as marked out for Racquets.

players," striking the ball above the line on the wall, endeavour to make it rebound to the outer courts; the "out-players" have to volley or strike it back first to the wall (always above line) to rebound within the inner courts. On failure, the opposing players score and serve. At Racquets the wall-line is usually about 2 feet 2 inches high, and the number of aces reckoned to game varies. At Prince's Club the rule is that the game be fifteen up. At thirteen all the "out-players" may set it to five, and at fourteen all, to three, provided this be done before another ball is struck.

Relievo, a rather rough, rushing, catching, and detaining game, engaged in by a greater number of players than the obsolete barley-break, which, in points, it resembles.

Riding is a very valuable exercise as well as a pleasant pastime, and may be profitably cultivated by all who can afford to own or hire a suitable horse. In many points riding on horseback is much better in itself, and conduces more to the enjoyment of various sports, than either cycling or carriage exercise; and it seems a pity that the cult of the automobile, or any other kind of wheeling, should lessen the vogue of equestrianism. The horse-rider requires to acquire, by tuition, or apt imitation, a graceful and easy seat, and

One of the fieldsmen stands ordinarily in front of each of the three out bases, the catcher behind the home base guards that. If the ball be caught in the air by the pitcher or any fieldsmen the whole side is out. If he be struck by the ball when running between bases he is out. He must endeavour to make ground as much as possible whilst a ball on or one of his side has struck is being fielded. No two players of the in side may occupy one base at the same time; but the last to reach it is out at the touch of the ball. The player who has made the round of the bases and reached home takes strike again when his turn comes, until all but one player of the in side has been disposed of by catching or running out. This last player may, by running a "rounder," get all his side in again: that is, he must, after the biggest stroke he can compass, run speedily round the whole of the bases and home again, before the ball is recovered and the home base touched by it. Such a ball must not be caught by any of the out side, neither must the striker be thrown at, or impeded by, the fieldsmen, all of whom must concentrate on getting the ball to the catcher or otherwise touching the home base with it before the striker's return. If the striker reach the first base only safely before being brought to a stand on his run, he scores but one for his hit; reaching the

second base unstopped counts two, and the third three, while a "roader" made usually reckons five. When the entire in side is put out, the fielding side goes in, and the team with the highest aggregate after a completed innings wins, unless two innings aside be agreed on for game before the start. When played with more than five aside the additional players on the out side scout in the country, which makes run-getting more difficult; but the game, fairly played, is a very good and lively one, not over complicated, and capable of conclusion within a reasonable space of time.

Rowing is a deservedly popular sport, as well as a useful art, and it moreover affords splendid and uniform exercise to the entire muscular system. It should be cultivated in some degree by all who have access to any kind of suitable boat on any safe water, for good oarsmanship gives great gratification and brings much physical benefit. To participate in this one does not need to be a racer or to undergo undue exertion. Rowing may be made either hard work or a pleasant pastime.

Running is more in the nature of recreative exercise than sport, and the inspiration to indulge therein, in moderation, should always be encouraged in the young. Running competitions, wherein the attainment and maintenance of great speed are involved, require to be prepared for by careful living and intelligently ordered training. The exercise, as such, comprises a succession of forward leaps, putting the muscles of the legs and trunk into healthy activity, and setting the lungs vigorously to work. At all stages of practice for pedestrianism of every character, it is advisable to avoid over-fatigue, and to desert from violent effort upon breathing becoming difficult and perspiration profuse. Great bursts of energy-expenditure are apt to make physical mischief. Exceptionally fine physique, very severe training, and the pink of condition are requisite to enable any man to run a mile in under four minutes and a quarter, as W. G. George did in 1886; or to accomplish the wonderful series of running records of Mr. A. Shrubal "out up" in 1902 and 1904, transcending everything before achieved on the track over distances from two to ten miles, the mark for which was reached by him in fifty minutes, forty seconds. Celerity and staying power may both be beneficially brought within the command of any person in health by temperate running; training and exercising at proper periods however.

Running at the Quintain. (See **Quintain**.) **Back Racing** provides sport of a comedy character at many summer pedestrian meetings and outdoor social gatherings, particularly to the on-lookers; the competitors get falls as well as fun for their pains.

Sailing in small boats is a pretty pastime, calling for tuition from an expert, and care on the sailor's part thereafter. The management of any kind of wind-driven craft in the water, where life is at risk, ought never to be adventured unless an efficient education in the art of sailing has first been obtained.

Sailing implies the propulsion of a boat by the skillful rocking movement, from side to side, of one oar over the stern; or by the use of an oar in each hand by a single-seated sculler. The latter is an interesting feature of many regattas, the former a desirable and utilitarian accomplishment.

Sea-Fishing, with line and baits, calls for the employment of strong and heavily-loaded tackle, with stout hooks and substantial floats. From shore, pier, or boat, satisfactory sport may often be obtained under favourable conditions of weather and tide, providing properly-attractive bait be used, such as cockles, mussels, small crabs, bits of fish, worms, etc.; while pieces of bright red cloth will sometimes be found a killing lure for mackerel. A very strong rod may be used effectively in a calm sea for some fish, but this is usually dispensed with by the marine angler. Net fishing in salt water is more of an avocation than a sport.

See-Sawing is a childish pastime, needing only a plank supported on a slight eminence, a boy or girl at each end, evenly balanced, to render it enjoyable.

Shinty may be dismissed with a reference to "Hockey," of which it is the Scottish variety—and somewhat ancient at that—as "Hurling" is the Irish.

Shooting is a field-sport to the elucidation of which libraries of books have been and are being devoted. The principal British sports with dog and gun are the shooting of grouse, pheasants, and partridges; and all these can only be indulged in in due season, under license, and by authorised persons, with proper observance of the law of trespass. Shooting for the purpose of attaining or exhibiting proficiency in marksmanship is hedged about by protective regulation, as it should be. Rifles and shot-guns are playthings for the privileged and the discreet.

Shuttlecock. (See **Battledore** and **Badminton**.)

Single-Stick, as differentiated from a variety of "Fencing" (see "Indoor Games" Section) was an old game of cudgels in which the player who first drew blood from his adversary's head was adjudged victorious. Since this kind of "Single-stick" was an extensively popular British sport, fashions have altered greatly.

Skating in the open on natural ice—necessarily in Britain only an occasional winter pastime—is most exhilarating and fascinating to the good skater. The necessary conditions precedent are safe and smooth ice, approved skates, and the ability to poise the body on the narrow ridge of steel firmly secured underfoot whilst moving in the desired direction, one foot relieving or assisting the other. Confidence comes of assiduous application; grace in executing the evolutions of figure-skating will follow. In most large centres rink-skating is procurable, rendering the devotion to the pastime independent of meteorological mutability at the cost of the up-breaking "snap" of frosty out-door air. (See also **Roller-Skating** in "Indoor Games" Section.)

Ski-Running is a sport peculiar to snowy and hilly regions, and the Norwegians and Finns are adepts thereof. The ski are elongated snow-shoes, 8 to 9 feet long, of smoothed, tough wood, upturned at the front. With feet tightly strapped to the centre of these, the ski-runner slips down a snow-covered or frozen incline, and, with the impetus gained, slides up a fronting hill, at the summit, when possible, leaping forward in the air to gain momentum for further glacial progress. Ski-runners in "full go" have been known to leap a hundred feet at a bound.

Skipping is not merely a girlish exercise; it is a pastime which, whether engaged in solus or with the rope "turned" by other hands, is recommended as good practice for athletes who desire to keep conditioned for football and other strenuous games. It keeps the breathing organs as well as the muscles in trim.

Sleighing, or "Sledging" is an alluring pastime on ice or frozen roads, whether the sleigh be drawn by hand or by horses, dogs, or other sure-footed animals, to whose harness are attached merrily tinkling bells. In Russia, Canada, and other lands where snow lies deep in winter the sleigh is often a picturesque necessity of transit.

Splapole. (See **Tether Ball**.)

Squash Rackets is an adaptation of the outdoor Racquet game (wall and ball) which has obtained some favour in the United States. It has no particular preferential merit over the orthodox pastime.

Stag Hunting is one of the old British "blood sports" with but limited lingering vogue. Where it survives a preserved stag is taken from cover beforehand, and carted to the meet to be released for the chase. The object nowadays is not to kill the animal, but to obtain the excitement of the running he may make for hounds and hunters. The Royal Buckhounds, an ancient Court appanage, were kept up as an active hunting establishment until quite recently; and there are still over a score packs of stag- or deer-hounds in England and Ireland. The season for buck-hunting in England is from August 30th to September 17th; the red deer may be chased from the first mentioned date to the last day in September; the hind is hunted in October and again between April 20th and May 20th.

In Ireland the pursuit of the male deer is legally allowed from October 20th to June 10th, and that of the fallow deer is practised between June 10th and Michaelmas.

Steeple-Chasing is the racing (a) of horses—necessarily leapers or hunters—over courses in which impediments in the way of more or less "stiff" fences and water-jumps are interposed, sometimes in combination; and (b) foot-races for lads, in which similar obstacles have to be surmounted. The horse and rider and runner on foot first covering the entire distance cleanly wins (unless a handicap allowance should have been arranged). Any failure to get "over the sticks" or "coming a cropper" at a water-jump puts the competitor out of the race. Obviously more skill and daring are needed in riding a steeple-chase than in horse-racing on the flat; and vigorous school-boys get good sport out of the foot steeple-chase. (See **Hurdles**.)

Stool-Ball is a very old English game generally regarded as a rudimentary form of cricket, now all but relegated to the use and progress of the great national summer pastime. Small sides of girls played stool-ball at one period with considerable frequency; and what was called "stools" was a more extended form of the game.

Swimming comprises the art of floating upon or in the water, and of progressing therein; a very desirable accomplishment indeed, as well as a pleasant and healthful pastime. It involves invigorating muscular exercise, with agreeable support to the body during its practice. The first thing to learn is how to keep the head above water; this is essential mastered, the movement of the limbs to compass progress can be entered upon with confidence. Harmonious flexion and abduction of the arms, and extension and adduction of the legs form the sum total of the science of swimming, as the ability to prevent the sinking of the head comprehends the whole art of floating. Natatorial exercises of the elementary sort should be taken in shallow water, and that near the shore, and in company of a competent swimmer for fear of cramp or panic paralysing the novice. When one can float or take a few strokes with comfort and self-reliance, more extended swimming may be essayed, until one is ready to plunge into the water for exercise or to save a life at any time.

Swinging in a suspended seat, the ropes and supports of which are sufficiently strong and firm, is pleasant exercise; for young children it should be gentle and "safe"; those of larger growth can generally be trusted to take care of themselves.

Tent Pegging is a feat practised in military sports: the taking up of a tent peg on the point of a spear or lance when at full gallop on horse-back. It is a survival from the old days of the tilt-yard.

Tether Ball. This is a game in which a ball is attached by a cord to the top of a firmly planted perpendicular pole, fixed on a lawn or other level ground, marked into two courts. The ball is struck by the players, standing, racquet in hand, on either side of the line marking the division between the courts in the centre of which the pole stands. Ball and racquet may be of lawn tennis, and the pole ought to be about 9 feet high with the cord for the ball 2 yards long. The game is sometimes called "Spiropole," because of the aptitude of the cord to twist spirally round its support after receiving a swinging blow. The players commence alternately; and at "Spiropole" the starter holds the ball in one hand with the cord stretched to its limit, striking it with the racquet with the object of winding the cord tightly and completely round the pole. The opposing player, keeping in his other court, endeavours to make the ball travel in the contrary direction, and whichever first completes a spiral scores a point.

Three-Leg Races are farcical events in which pairs of participants are set to run in competition after having the right leg of one of each pair bound to the left of the other. Tumblers and hilarity result.

Throwing the Hammer. This is a feat of strength and agility practised at athletic sports meetings and game gatherings. A hammer with a 16 pound head and 4 feet handle, grasped with both

hands, has been thrown 113 feet 11 inches in America. In Britain, a 16 pound hammer, swung in a 50 feet circle, was thrown by J. Flanagan 163 feet 1 inch, while the United States record for a similar feat is given as 175 feet 4 inches.

Tig is a juvenile game in which one of a crowd of dodging, running players tries to overtake and touch one of the others, who then becomes "tig," and has to take up the pursuit. "Touch" and "Touch and Go" are the names given to this pastime in some places.

Tilting at the Ring is an equestrian exercise, in which the object is to get the point of an extended lance, whilst riding at full speed, through a suspended ring deftly disengaging the weapon without losing hold of the shaft, and avoiding being unhorsed. It possesses some semblance to the old sport of "Running at the Quintain" (q.v.).

Tobogganing is sleighing down hill, and is very popular in Canada and elsewhere on natural snow-tracks. It is practised also on artificially prepared "switchback" slides, the latter ending often in a "shoot into water." The toboggan is shaped something like a flat-bottomed boat. The pastime in any form is exciting.

Top Spinning. This is a pastime affording perennial delight to a small boy, requiring a smooth surface and a top of one of three kinds to spin thereon. The peg-top is pear-shaped, with an iron or steel prod at the small end. It is tightly wrapped round with a string, beginning at the peg and winding upwards, and then thrown forcibly on the ground, point downwards, the string being released deftly in the cast, to impart rotatory motion. The whip-top is a wooden inverted conoid, kept spinning on the point by blows from a leathern lash. The humming-top is a hollow metal globe on a pointed central stalk, round which a fine string is wound closely and evenly, being introduced through a hole in the side of the sphere to one in the spindle opposite thereto. The top being held firmly near the floor with the left hand, the string is pulled away with swift, strong traction, on its outer end by the right.

Trap, Bat, and Ball. A game deriving its name from a kind of trap (varied in form and construction in different places) being employed to spring the ball into the air to be struck away by the batsman. Sometimes it is called "trap-ball" simply. (See **Dab** and **Trigger and Knur and Spell**.)

Tug of War. This is a game in which opposing sides of equal number (usually seven a side) pull in different directions upon a stout rope, in the endeavour to draw some portion of their opponents half over a central mark or scratch. A prescribed length of play from centre is allowed to each party of tuggers; if this be pulled over, those gaining the ground (or rather, length of rope) score. Concerted tension, strong and long pulling, and firm foothold are factors in the conquest. In Canada in 1877 two teams pulled against each other in a tremendous "tug of war" lasting two hours and ten minutes, without either holding an advantage over the other sufficiently long to secure a win.

Vaulting. (See "Indoor Games" section; also **Pole Jumping**.)

Walking comes naturally as a pastime to man, he being anatomically constructed for locomotion in the erect posture, and there is no exercise more conducive to continuous good health. The alternate forward motion of the legs and feet procures progression, but every limb is called into activity by pedestrianism, and the circulation of the blood stimulated throughout the system. Learn to walk gracefully, and for a reasonable distance regularly without fatigue. Even prolonged walking, in good air, beyond the tiring point, is salutary, but for the ordinary purposes and convenience of latter-day life, it is not often necessary, except for observation purposes. Yet one should be capable of long and quick walking, though there is no occasion to aim at emulation of the speed or endurance of Mr. W. J. Sturges, who walked a measured mile in a trifle over six and half minutes, fair heel and toe, covered well over eight miles an hour, and thirteen miles in just under one hour and forty-three minutes.

Water Polo is handball in the water, with ball and nets and side formation very much as for football. The ball may be used on the head, back-wards and forwards as in the land game; but the players must not touch bottom with their feet when they are passing with the hands or a "foul" will be whistled for by the referee and penalised. A player holding the ball may be immersed to make him relinquish his hold, and the players must not swim to strike from an "off-side" position.

Wheelbarrow Racing is a comic sport in which one person walks forward on his hands the while his feet are held in their by a partner walking in step behind him; the two competing with other pairs in similar plight to first gain the winning post. It always makes an amusing contest at a gala gathering.

Whippet Racing. This is the pitting together of speedy, long-legged, short-bodied, running dogs, of specially-bred, modified greyhound form, in time races, a sport very popular with the pitmen and other workers of the North of England. The whippets are fed and trained regardless of expense, relatively speaking, and prized by their owners often beyond any other possession. They run in heats, on courses contiguous to large towns, being started at pistol shot by release of the slipper's hold on the skin of the neck and the tail above the raised hindquarters. Some whippets can tear along at a rate of over seventeen yards a second.

Wrestling was a feature of the Olympian games of the ancients, and a modification of the method there employed has survived to our day in the Greco-Roman style. Wrestling is also still practised by athletes of great prowess in Cornish, Cumberland, "catch-as-catch-can," and other strenuous styles; more often, it must be admitted, as a more spectacular display than as bona-fide attempts of the participants to do their best to overcome each other; and usually in an indoor arena. In all descriptions of wrestling the endeavour is for one competitor to give the other a fall, either by means of leg hold, wrist hold, or body hold, or by combined grappling and heaving. The back-hold and the struggle to maintain the perpendicular are of the Cumbrian and Westmorland style

of wrestling as exhibited at the Grasmere and Morpeth sports; the grip, on the upper trunk was played for, often for half an hour—until Devonian and Cornish rules, in which kicking was permissible; "catch-as-catch-can" is the chief characteristic of the Lancashire style, that is to say, the wrestler is allowed to take any hold whatever, of the head, trunk, or legs, and maul, haul, grip, and struggle to break his opponent's two shoulders to the ground. Modern Scottish wrestling combines the Cumbrian and Lancastrian styles; Irish wrestling differs again in admitting only the hold upon the elbow with one hand and upon the collar with the other, which must be maintained, the first of the twain going to earth being vanquished. Tripping and sleight of foot are prohibited in the so-called Greco-Roman style prevalent in Continental Europe, in which ground-struggling and sheer weight and strength count most. In one respect all wrestling is alike, there is nothing gentle about it, whatever on subtlety or grace it may exhibit in addition to the employment of physical force. (See also, *Jiu-Jitsu*.)

Yachting is a fascinating sport, both as regards the management of sailing pleasure vessels of light or large tonnage, and the enjoyment of the more expensively fitted steam yachts—now so common—whose owners may assume the proportions of floating hotels. It is calculated that their aristocratic and wealthy owners have sunk in the combined fleets of sailing and steam (or otherwise propelled) yachts which to-day have a place on *Lloyd's Register* as much as ten millions sterling; and their upkeep and maintenance of their crews, with club subscriptions, etc., runs into nearly a million a year. Probably the proprietors of, and guests upon, the smaller yachts, who actually participate in the navigation, get more actual satisfaction from their invigorating aquatic hobby than do the crowned and titled yachtmen who lay themselves out to enter cup contests at enormous cost; anyhow the furling and spreading of "white wings" and sailing over flowing seas at will is a sport at once thoroughly British, healthful, and pleasing. The yachting meetings at Cowes and elsewhere are also always gay and picturesque social functions, given propitious weather.

SECTION II. INDOOR GAMES.

Amusements, Indoor. All the popular indoor amusements, whether games or exercises, are dealt with alphabetically in this section, dances and card games being grouped together for facilitation of reference.

Acting Charades. Choose a word of two or more syllables, each of which is in itself a word capable of simple scenic illustration. Let the ablest mimics of the company, directed by its most resourceful member, act each syllable of the word separately and in order, in a little scene, mirthfully and with all available accessories, lastly presenting a scene properly descriptive of the whole. This makes a good charade. Introduce the key syllables and word into the dialogue, others only indicate it dramatically. Examples of good words for acting charades are "Pen-man-ship," "In-fan-try," (making the first scene an inn), "I-sing-las," "Sup-port-able," "Break-fast," "Fret-work," etc. The things to aim at are variety, fidelity to the subject allied with skilful mystification, and spirited comedy with picturesque dressing.

Acting Proverbs, though otherwise somewhat similar, require a little more preparation than Acting Charades, as some plot must run through the representation of the chosen maxim, which should be a familiar one, the actors endeavouring to delineate its moral. The number of acts required may be varied; thus "A rolling stone gathers no moss" can be presented in two preliminary scenes and a final act devoted to the enforcement of the moral of the proverb.

All Fours. (See Cards.)

Baccarat. (See Cards.)

Backgammon. Requisites: a board or table; fifteen black "men" or pieces, and fifteen white ditto; dice and cups to cast them from. The board is divided into two equal parts by a central bar, and on each half are marked twelve points, six at either end, white and

black alternately. The "men" are placed in the beginning as evenly as possible on points at the opposite ends of the two half tables, eight white pieces, on white points on White's end, and seven black pieces also, on black points, at the same end, with eight black pieces and seven white ones correspondingly disposed at Black's end. The game—which has numerous complications—goes in favour of the player who has first been able to move all his men to the proper points on his own table, and play them off, or bear them away, by means of fortunate throws of the dice. This makes a game of the day, which accomplishes this, before his adversary, by throw gets his men placed in the opposite territory, wins a gammon. A gammon is equal to two hits, and the winning of two games out of three gives the "rubber." Luck has as much play as skill at backgammon. The player who makes most use of his chances wins.

Bagatelle. A table game with balls and cues, the table being much smaller than the regulation size for billiards. It is covered with cloth, and measures from 5 feet long upwards, by 18 inches or more wide, cloth covered and surrounded by a cushioned rim, semi-circular at the top end. Here are disposed eight cup-like holes in a circle, numbered from 1 to 9, the highest hole being the middle one. In front of the first hole is spotted a black object ball. From opposite to this, at the bottom end, in baulk, the first player strikes to hit the black ball and thereafter get his own, or it, or both, into one of the marked holes. The striker follows—in the English game—with seven other balls, holding as many as he can. With each of his strokes he must, to score, first strike the black, and if the black be holed it counts double. Thus if it is driven to rest in the central or 9 hole, the black object ball counts eighteen towards the score of the striker.

Any shot ball coming back over the half-way line is removed as "dead." The total number of the values of the holes filled with the eight shots is marked towards game (a number fixed beforehand for the striker; then his opponent follows with eight strokes. The one first reaching the agreed aggregate number for "game" in an equal number of visits to the table, or making most in an equal number of tries, according to pre-arrangement, wins. **The Cannon Game.** This is bagatelle with only three balls in use, as at billiards. The black object ball is retained, and the opposing players have one a white and the other a red ball to strike with. The black ball is "spotted," and the ball of the non-striker placed on a mark behind it in the middle line of the table between the 1 and 9 holes (the first and middle ones of the circle). If the striker can with his own ball hit first the black and then his opponent's with his own struck ball, he makes a cannon, and counts two towards game. Sometimes these cannons, which are continued by the striker as long as he can score, are alone counted; sometimes the value of any holings made during the striking are added. When the striker breaks down, his adversary takes up the game; and who gets to a given score first is victorious. **Mississippi.** In this game a nine-arched barrier is placed as far up the bagatelle board as possible, and all the balls are sought to be holed, its interposition notwithstanding, with the added proviso that a side cushion must first be struck, otherwise the score resultant is marked to the opposing player. **Sans Egal** is a further variety of Bagatelle, in which, the black ball having been spotted, each player shoots alternately with one of four balls, red or white respectively. All the white balls holed by White count to him, with the black double if he can manage it, and all the red balls he holed to his adversary, and *vice versa*. **French Bagatelle, Russian Bagatelle, or "Shooting up the Board,"** is played on a table—often much smaller than an ordinary Bagatelle board—having a partitioned channel reaching nearly to the semi-circular top on both sides, and the centre studded with pins or pegs formed in circles, each with a small upper entry, and so disposed as to allow channels between. Every circle is numbered low numbered ones being in juxtaposition with those higher; and the highest of all has a bell fixed within it firmly. A small glass ball is shot, by pulling a string, from the left-hand groove, up the board or table, which is slightly inclined towards the player; his aim is to impart just sufficient force to carry the ball to the top, so that it may roll gently down into one of the pinned circles, and there lodge, when he counts the number marked in the hole occupied towards his aggregate score. If the ball roll down to the bottom by the right-hand groove, it does not count; should it ring the bell, the score of its ultimate rest-place is doubled. A slight variation of this game is sometimes styled "The Devil amongst the Tailors."

Ball Games, Indoor. (See Bagatelle, Ball-punching, Billiards, Bowls (Table), Court Tennis, Ping Pong, Pool, Pyramids, Nine Pins, Skittles, etc.)

Ball-punching. The striking of a large inflated ball, suspended by a cord, with the fist, and avoiding the recoil; an athletic exercise of some value in keeping up muscular condition.

Bar-balls. Bar-balls, of variant weight, with a uniting rod, a yard or more in length, for use with both hands in physical drill and gymnastics. (See Dumb-bells.)

Basket Ball. (See Outdoor Sports.)

Basset. (See Cards.)

Bélique. (See Cards.)

Billiards. A ball game of skill and precision, played with a cue on level and smooth rectangular table, covered with fine green cloth, with balls of ivory or bone or bone composition. The table is enclosed by cushioned sides, two to three inches high, having netted pockets at each corner and in the centre of both long sides. The inside measurement of a full-sized table is 22 feet 8 inches by 5 feet 10 inches. Three balls are employed in the ordinary billiard game; a red one, which belongs to neither player, but is "spotted" on

a small mark placed centrally on the table about a foot from the end and furthest from that the striker starts at, and two white ones, one for each player to strike with. Of these one is distinguished by a small black speck, and is called "spot," the other being "plain." One of the players "breaks," by striking his ball from a half-circular space marked behind the baulk line opposite to where the red is spotted. If he hit the red and drive it into any pocket he scores three, or should he own ball, after striking the red, roll into a pocket, he also scores three, both balls resting in pockets after a stroke counting six to the striker. The red is replaced on the spot every time it is holed, and can be shot at from the position in which his own ball comes to a standstill. Should a miss occur by the player in possession of the ball, one is scored by the opposing player, who thereupon takes strike. Should the striker's ball, on a miss, enter a pocket, three is scored by his antagonist, but the lost ball remains in the pocket, leaving only the red to be played at. It is usual for many billiard players to give a "miss" at the start, in order to get two object balls on the table for subsequent play; this is done by the striker playing his own ball out to a cushion intentionally, to roll back within baulk, when the white cannot be played at by the player who follows until the red shall first have been hit. This is giving one away to open up the game. With one white and one red to aim at, if the striker with his own ball hit both object balls he makes a cannon, which counts two. The red ball entering any pocket as a resultant of a cannon shot counts three additional to the striker, for the winning hazard, the white being holed eventually, having first struck the red, whether a cannon be made or not, counts three for the losing hazard, when the striker must make his next shot from baulk. It is possible for ten to be scored from one stroke, by striking the red first, making a cannon, and holing all the balls; but this has the disadvantage of compelling the striker to break again from baulk, with only the red as objective, the opponent's white being out of play until the striker fails to score. Cannons are made frequently by players from strokes in which a cushion is struck at a tangent before the object ball is hit; and the great thing in the game is to score as many as possible, leaving the balls in a position unfavourable to the opposing player. The ultimate failure to score then becomes "playing for safety." Nursery cannons are those made with the object balls nearly together and without leaving them in a position more difficult to score off after the impact. The striker's ball is impelled forward by a distinct strike with the cue, the thin end of which protrudes over a "bridge" made by placing the left hand on the cloth, palm underneath. The cue is held by the heavy end in the right hand, and run forward between the forefinger and thumb of the left with sufficient force to give the required impetus to accomplish the stroke advertised, the object balls or cushions being struck in such a manner as to obtain precision of movement, after the object for the striker's ball, and also for those aimed at and moved by the stroke. The player's break continues until he fails to score, when his opponent goes to the table and continues the game. Generally a game is for 50 or 100 "up," the player first having the agreed upon number marked in his favour winning. Four players, two against two, may have part in a game of billiards; the "plain" and "spot" partners taking stroke alternately.

Pool. This is a game on the billiard table, all of winning hazards, in which, by the employment of various coloured balls, several players may participate, playing in the order in which the colours appear on the scoring board, and each player plays on to the ball preceding him. Every time a ball is shot at it is holed, the owner of it in the game loses a "life," and the striker thereafter plays at the ball nearest on the table to his own until he fails to hole a ball. The striker, if he make a losing hazard—that is, if his own ball should run into a pocket—loses a life. Each player has three lives; and when all but one player has lost these, the survivor takes the "pool," or, two being left in with an equal number of remaining lives may divide the stakes. **Snooker** is a modification of "Pool."

Pyramids is played with fifteen red balls, placed pyramidically, by the aid of a light frame, near the head of the table, the apex towards the first striker with the white. He of two players who holes the greater proportion of the red balls wins the game. Every time the striker fails to score or holes his own ball, the adversary plays with the white, from bulk if lost, or from the position in which it remains on the table otherwise. The maker of the losing hazard, in addition to yielding strike, has to replace a captured red ball on the table, or owe one to his opponent should he not have scored. Variations of this method of pyramid play, in which many billiard rules hold good, admit of three or more players participating.

Blind Man's Buff, a merry, romping game in which one, blindfolded, has to catch and name some other player, who then becomes "blind man."

Bowls, Table. A parlour adaptation of the game of lawn bowls, miniature biased bowls being shot along a polished table from a grooved tilt shoot.

Boxing a combined sport and exercise, when proper gloves are employed, is a useful and commendable art, inculcating the principles of self-defence and the scientific use of the fists in a just quarrel.

Brag. (See **Cards**.)

Bridge. (See **Cards**.)

"**Buz**" is a forfeit game for children, in which the seated company count audibly from one upwards, the participant whose turn comes at any seven or multiple of seven having to substitute the word "Buz." Thus, instead of "seven," "fourteen," "seventeen," and so on, "Buz" must be called out or forfeit paid.

Caledonians. (See **Dancing**.)

Calisthenics is a term comprising numerous exercises designed to give mastery of graceful muscular motion and bodily carriage, *satis* or in concert with others. Its systematic cultivation, with proper regard to the strength of the subject, is good athletically, and as a mere matter of pastime also. Competent guidance in calisthenics is desirable.

Cannon Game. (See **Bagatelle** and **Billiards**.)

CARDS.

Cards for playing with in various ways are of very ancient vogue, in East and West, and have changed a good deal as to name. Those in present use are fifty-two to the pack, in four suits of thirteen each; clubs and spades being black printed, hearts and diamonds red. Every suit consists of three court cards: king, queen, and knave (or Jack), and ten numbered cards. The latter are marked with from one to ten printings of the suit device, the higher being of the greater value in most games, save that the ace usually takes precedence of all, even the court cards. The following paragraphs cover the leading games with playing cards.

All Fours. Six cards are dealt from a complete pack, the thirteenth being turned up to indicate trumps. The hands are played, the greater capturing the less in each trick, and trump cards those of any other suit. The points are High, Low, Jack, and the Game; the latter being the querdon of the possessor of the greater number of counting cards, their values running: aces, four; kings, three; queens, two; Jacks, one; and tens, ten. The point High goes to holder of the highest trump dealt, Jack to the retainer of the knave of trumps, should that card be dealt, Low to the person playing the smallest trump, whether retained or not.

Backgammon. A gambling game, illegal in Britain, in which one player takes the bank against several others, doubling what they stake. Two cards are dealt to each player, the holder of the highest hand taking the stakes, the banker's hand being "trumps," which are of greater value in the game than anything of other suits. All the court cards are worth ten each, the rest in accordance with the pips.

Basnet. A gambling game, played between a banker (who has an assistant, to supervise the losing card) and the punter, opposing the bank.

Bézique. This requires a pack of cards for each player, all the low cards from six downwards being

dispensed with. Four or three may play the game, though two is best. The cards being shuffled together and cut, the dealer gives eight cards to his opponent, and the same number to himself, the seventeenth card being turned up to indicate trumps. Then the non-dealer takes a card, to which dealer plays, the best card winning the trick; play proceeding as at whist, save that ten will take any card except ace. The winner of the first trick takes the top card from the undealt remainder of the pack, his opponent takes the next. Then another trick is played, and another card taken by each and so on till the pack is used up; whereupon the remaining eight are played out in tricks, till all are lost and won. Scoring depends on the combinations held and declared after each trick, the player first reaching 1,000 being accounted the winner. Thus, the winner of a trick who thereby becomes the holder of all four aces registers 200 points towards game, four kings 80, four queens 60, four knaves 40. Simple marriage (king and queen, same suit) scores 20 points, royal marriage (king and queen, trump suit) 40; bézique (queen of spades and knave of diamonds) 40; double bézique (the two queens of spades and both knaves of diamonds) 500; sequence (ace, ten, king, queen, and knave of trump suit) 250. Seven of trumps played or turned up reckons 10, taking the last trick 10, and finally every ace and ten in the captured tricks counts 10 to the taker.

Blind Hookey is a simple game of chance at cards; comprising cutting and speculating as to the turn-up.

Boston is like whist, played four-handed, save that the last card is not turned up to make trumps. The player declaring to win most tricks leads, and makes trumps, providing always that he may, if he consider himself unable to win more than seven, ask for a partner. On being accepted, the two play against the remaining pair, as at whist. Also any player, there being no declaration above seven made, may undertake, *solo*, to get a number of tricks less by two than the provisional caller; and, if there be no partnership, the three players not having called endeavour to frustrate the play of "Boston," the *solo* high declarer, or "whist," the low-caller who deprives him of lead. If declarer or partners achieve their undertaking they take the pool; if they fail they are mulcted. Dealer subscribes half as much more to the pool as the other players. "Boston" or "Booston," very much resembles the game now known as "Solo Whist."

Brag is a game in which three cards are dealt to each player. A declaration is made by one to win two or three tricks, and if this "brag" be not exceeded by the players to his left, he proceeds to make the declared number and win, or to fail and lose.

Bridge is a development of whist, with complications, and is very popular in many circles. There are four players, and in each hand the dealer's partner takes no part in the play, but exposes his cards for the dealer to use as in dummy whist. Trumps are declared by the dealer or his partner (dealer having first option), without consultation, or they may elect to play without a trump suit. The tens, as well as the court cards, are honours, but honours do not count towards winning the rubber, being added to the trick score afterwards to determine the value of the rubber. There is a score for winning "little slam" (twelve tricks), and a higher score for "grand slam" (all the tricks); also for "chicane" (holding no trump in a hand). The scoring of points is an elaborate affair needing special instruction.

BRIDGE SCORE.

Score by Tricks.

♠ for each Trick, above Six, when ♠ are trumps.			
4	"	"	♣
5	"	"	"
6	"	"	♦
7	"	"	"
8	"	"	♥
9	"	"	"
10	"	"	"
11	"	"	"
12	"	"	"no trumps."

Score by Honours.

	♠	♣	♥	♦
Three Honours = . . .	4	8	22	16
Four Honours = . . .	10	16	24	32
Five Honours = . . .	18	20	30	40
Four, all in one hand =	16	32	48	64
Five, four in one hand =	18	36	54	72
Five, all in one hand =	20	40	60	80
Chicane =	4	8	12	16

No Trumps (Sans Atout).

3 Aces =	30
4 " in one Hand =	40
4 " =	100

Grand slam, 40; little slam, 20; rubber, 100.

The game is finished when 30 has been won by *Tricks*.

Casino is played by two, three, or four persons, with an entire pack of cards. Four cards are dealt to each player, and four on to the table, face upwards. Then the players in turn match what they can from their hands on the cards on the table, by pairing or taking two or more up, the pips of which will together equal those on one card held by them. These they win and turn down alongside them. If they cannot pair or match they must lay a card down. When the first deal is played out, another deal round is made to the players until all the cards are exhausted. The game is to capture all the cards you can, and as many tens, spades, and aces as possible. High (or Great) Casino—possessing at the close of a hand the ten of diamonds (two points); Low (or little) Casino, the deuce of spades (one point). "Cards" is when players (or partners) capture a greater share of the counting cards than the opponents, which reckons three points. "Spades" is having the majority of that suit, one point. Aces each reckon for one point. Should all these eleven points belong to one player (or pair of partners with the same high), that player is marked to them and the game ends. Anything held against the preponderating hands in opposing hands is deducted, and the game proceeds until concluded by eleven being scored by one player or pair.

"**Catching the Ten**" is a simple game, resembling "All Fours" and "Don Pedro," except that the greatest point considered is the capture of the ten of trumps by the ace or a court card of the same suit. It will take any other ten, and, of course, any card of a non-trump suit.

Connexions. A rather antiquated game for three or four players; dealing out eight cards should the greater number engage, and ten if the smaller. Card values and manner of play as at whist, save that diamonds are always trumps. The "connexions" to be made are the two black aces, the ace of spades and king of hearts, and the ace of clubs and king of hearts. The player of the first card makes the "connexion," and secures it, unless trumped by a following player. The seizer of the last-mentioned "connexion" and the winner of the majority of tricks take an equal amount from the pool; the maker of the second "connexion" double what goes to either of these; and the fortunate maker of the first-mentioned "connexion" double what the second winner withdraws.

Cribbage. Dealer serves out either five or six cards from an entire pack. Two cards are thrown out by each player, but not exposed; then a card is turned up, and this counts with the crib (which belongs to dealer), and also with the hands of the players. In discarding, and in play, the endeavour is to make as many combinations of fifteen, pairs, and runs, as possible; and "flushes" also count, i.e., all the cards held being of one suit. The court cards are valued at ten each for counting, and the rest according to the number of their pips. Sixty-one points is game when two play at five-card "crib"; twice round the board at six cards. There are further points in the game, for which instructions should be obtained.

Don Pedro is similar to *All Fours* and "Catch-

ing the Ten," except that the capture of the five of trumps, which is "Don," is the chief point in the game, and that all the five count in reckoning the hands as well as the tens, aces, and court cards.

Dummy Whist is *Whist* (q.v.) with three players only, the fourth hand being taken in turn by the dealer, and played in addition to his own hand, against those of the other two players. "Dummy's" hand may be exposed on the table, or otherwise, as arranged.

Ecarté (sometimes called "Discord"), is played with the kings, queens, knaves, aces, tens, nines, eights, and sevens of the pack ranking in value as named; and sometimes two packs are employed. Five cards are dealt to each player (two or more may play), and the succeeding card is turned up for trumps. There may be discarding and changing for fresh cards from the "talon" or undent portion of the cards for play on proposition, and the game—which is of gambling notoriety—has other complications.

Euchre is a modified form of *Ecarté*, the master card being the "joke," the second master card of the same colour the "right" bowler, the next, the other knave the "left bowler." To "euchre" the opponent is to take three out of the five tricks in a hand. A gambling game, popular in America.

Faro, a speculative game, in which players oppose the banker, at a special table, using the entire pack; odds being in favour of the bank.

Loo is a round game in which a number of players can participate. It may be three-card or five-card loo, the former permitting the greater number of players; and it may be "limited" (in which those "looted" pay into the pool counters to the value of their original stakes) or "unlimited" (in which the forfeit is equal to the whole amount of the pool). Winners take an equal proportion of the pool for each trick captured. Those who do not win a trick are "looted." At five-card loo a flush of trumps, or four trumps with "Pam" (the knave of clubs) takes the entire pool without playing, and all the rest save the possible holder of "Pam" are "looted." There are other complications, for which we have not space.

Lottery is a game in which players speculate on their cards as against those of their opponents, and then play for the stakes and the pool to which all contribute. In parts "lottery" resembles *Rouge et Noir*.

Matrimony is played with counters and the full pack, the dealer staking what number of counters he or she likes, on each of the five chances in the game, and the rest (5 to 14 may play) placing one less piece on the chances. Two cards are dealt to each, and then a third turned up to every player. The ace of diamonds turned up to any player clears the pool in that player's favour. The chances are:—Best (ace of diamonds, turned up); Matrimony (king and queen); Confederacy (king and knave); Intrigue (queen and knave); and Pairs (the highest pair). Should any combinations be held in more than one hand, the eldest hand takes; and failing the holding of a chance, the stakes thereto allotted go forward to the following deal.

"Nap" or "Napoleon." Five cards dealt singly to each player from full pack. Player or dealer's left "declares" to win what number of tricks he thinks he can—two, three, four, or "Napoleon" (the whole five) or, with a poor hand, "passes." The next player has the privilege of calling higher and taking the lead in that case, unless he himself be over-called. The first card played by caller constitutes trumps. Should the leader "make" the number of tricks he declares he receives stakes as previously agreed from his opponents; "failing" he "pays out" accordingly. In a "Nap" declaration the "pay out" for failure is generally single, and for success double, but the arrangement may be varied. With an exceptionally poor hand "Misère" may be called by any player and take precedence of all else (unless another calls three). Here the caller's task is to avoid winning any trick, and forfeit or gain are usually as for three tricks. "Nap" is a favorite fast gambling game for small stakes with many card players.

Old Maid is a simple round game. From the pack a single card—generally a black queen—is extracted, and the rest dealt round, one at a time, to a number of players; who pair and place on the table all they can, and then in turn draw a card from the next hand to enable them to complete the pairing. The first to pair all his or her holding wins; and one left with the odd card at the end is "Old Maid." An odd overplus may lie left on the table after dealing the rounds to be drawn from by the last two or three players left in.

Ombre, a Spanish card-game, played by two, three or five (generally three) persons, once popular in Britain, now obsolete.

Patience is a game played singly with an entire pack, though several persons, with a pack each, may play simultaneously and endeavour to beat each other "on time." There are several variations of the game, the object of which is, by dealing from the shuffled pack all the cards, one by one, to get them into sequence or ace at the bottom to king at the top, in all the suits, as quickly as possible. When the top card of any tentative pile cannot be moved on to one of lower value in another heap, the cards not properly disposed of are taken up, re-dealt, and new manipulation adventured. Should an impossible "block" be arrived at, the player must commence all over again.

Piquet is a complicated game for two, the cards from deuce to six inclusive of each suit being dispensed with. Ace ranks highest, counting 11, the court cards reckoning to, the rest according to the number of their pips. Twelve cards are dealt to each player, the eight remaining forming stock, to be drawn from when the cards of least value have been discarded by the players. The main chances striven for are Rejque, Pique, and Capot, worth 90, 60, and 40 respectively towards the full game of 100 points. These and the other features of Piquet require lengthy explanation, as given in handbooks of the game. Play is as at whist, but with no trumps.

Polo is a game of hazard, with numbered "chips," all the cards, and not more than six players, greatly in vogue in America, and popular at many British clubs. It is not commendable as a parlour pastime, because of its gambling associations.

Pope Joan is a round game for a number of players, similar in many respects to "Matrimony" (*q.v.*); the chances speculated upon being Pope Joan (nine of diamonds), Matrimony (king and queen of trumps), Intrigue (queen and knave of trumps), ace (of trumps) and Game (first out); "pools" being made at the commencement on a special board in respect of each of these points. "Stops" are a prominent feature in play, and the eight of diamonds is withdrawn from the pack before dealing begins. For "Pope Joan," once a very popular social pastime, some instruction is desirable.

Put is akin to "Brag," but the "trays" are of highest value, deuces next, then aces, with the rest, from kings to four downwards, as at Whist. The entire pack is used, and two or four can play. Three cards only are dealt separately to each player, and there are no trumps. If the non-dealer be dissatisfied he may throw up his cards, losing a point. The adversary, calling "I put," the other player may refuse to play, yielding a point, or he may play and win or lose. Two tricks of three taken by either player scores five points and wins the game, but one trick each, and the third a tie counts nothing to either. If four play, three cards each are dealt, and one of each pair gives his best card to his partner, who discards his weakest in lieu thereof, and the game proceeds as at two-handed "put." It is a quick, "bouncing" game.

Quadrille is an old-fashioned and very involved game for four players, with forty cards, the tens, nines, and eights being rejected. Its numerous terms and rules require lengthy demonstration.

Quinze is a simple game of chance. The dealer, after shuffling, gives his adversary and himself a card each from the full pack. The non-dealer is then entitled to go on drawing from the deck until the cards he holds count fifteen or nearest thereto, when he wins; but if he overdraw he loses, unless the dealer does the same, when the game is drawn. Thus, being dealt, say, an eight, he draws seven and wins; but,

drawing six, he "stands" at fourteen. The dealer must then draw; and should he hold a tenth card and draw a five, becomes victorious. Drawing six, however, would constitute overdraw and defeat.

Rouge et Noir, played with six packs of cards on a table covered with green cloth and marked in red and black diamonds, is a Continental gambling game of an exciting nature, in which high stakes are often involved, with heavy odds against the "punter," and in favour of the "bank." This hazardous game is also called *Trente et quarante* and *Trente-un*.

Snap is one of numerous childish round games, in which cards of several (usually thirteen) different pictorial devices (four of each pattern) are dealt out singly and successively to the players, one being laid centrally on the table after the first round is dealt, and all face uppermost. Whoever of the players first cries "snap" upon the facing of any card of similar design to that on top of his or her own pile or that of any other player, or in the pool, appropriates the pile called; in the latter case sweeping the pool also. The player eventually holding all the cards takes the pool at the finish, if being replenished by the deposit of further stakes after each depletion until the cards are out. Nuts may be employed as stakes by the juvenile players of this merry game, which is subject to variation. In **Snip Snap Snorum** the cards dealt to the players are held in their hands—an ordinary pack of playing cards being used—and played in turn. When the following player can match the card played before him he does so, cries "Snip," and takes the card and a forfeit. A third player, matching, cries "Snap," and does ditto, while, on rare occasions, a fourth may call "Snorum," and profit accordingly. A player having lost all his, or her, stakes—they start with an equal number of counters—and cards, is out of the game. Ultimately, the pool becomes the property of the player holding out longest.

Solo Whist is a game in which the four players act independently, unless there be "proposal" and "acceptance," when the two partners play together against the other two. Play is as at Whist, honours, however, not being counted. The cards are all dealt, in four threes and the final round singly, dealer facing his last card to indicate trumps. The player on dealer's left may then "declare." If he, with a fairly strong hand, thinks he and a partner could make eight tricks, he calls "I propose," and may be accepted by any one of the other players in their turns, when the game proceeds, should there be no higher call. He may, however, call "Solo," which is a declaration that he intends to try to win five tricks against the combined efforts of the other three players. He may go higher and call "*Misère*," which means that he undertakes not to win any trick, and in this call there is no trump suit. He may declare still higher, called "*Abondance*," and, to make it, must win nine tricks, making any suit he chooses to denominate trumps, always providing that a call of *Abondance* on trumps would have precedence of that call in a non-trump suit, and take from him the lead. A very poor hand does not "declare" but "passes"; though the first player to call, having "passed," may accept, a proposer, should the other players not do so or make a higher declaration, the declarations ranking from *Abondance* downwards, the lead going by rotation. The stakes are graduated, lower, paying out to the other players on failing to achieve their declaration, and receiving upon accomplishing it, with additional winnings per trick exceeding the declaration, and forfeits for each of the declarer and not taker, and for winning any trick after calling *Misère*. *Open Misère* is a higher call than *Abondance*, its declarer exposing his hand after the first trick; and *Abondance Déclaré* is the highest call of all—in which he who adventures upon it must take every trick. Double receivings and forfeits obtain in the last two calls, as compared with simple *Misère* and *Abondance* respectively, though there are no under tricks or over tricks to be paid for.

Speculation is a lively round game, in which seven to thirteen may participate—"the more the merrier"—with a complete pack and counters. Three

cards are dealt to each player singly from left, and then one—which belongs to dealer—turned up for trumps. This may be speculated for by offers of counters, before or after the turn-up, and sold to the highest bidder. Stakes are placed in "the pool," the dealer usually contributing double the number of counters paid in by each of the rest. The next player, or in the event of the card having been sold the next player to the purchaser, then turns his top card—which must not have been looked at by him or anyone else—and if it be a higher trump than the turn-up, he may sell it as he chooses. The player to left of new purchaser then does ditto, and when all have been discovered, the possessor of the highest trump—by purchase or otherwise—in the deal clears "the pool." The game is continued similarly by further deals until the pack is exhausted,—the cards counting as at Whist—the highest trump in each deal taking "the pool."

Vingt-Un is like **Quinza** (*q.v.*), except that the number to be made up by cards drawn after the first deal is 21 instead of 15; and the ace counts either as one or eleven, as he who gets it chooses.

Whist is accounted the best of all social card games, and is played according to rigorous methods and strict rule by four persons—two in partnership against the other two—and the complete pack. The partners sit at opposite corners of the table; and, the cards having been shuffled and cut, are dealt out singly until exhausted, the dealer turning up his own thirteenth card to indicate trumps. The cards are then taken in hand and played out in 13 tricks of four each, the player on the left of the dealer having first lead; and the winner of each trick leading off in the next. Ace is highest card—except in cutting, when it is reckoned lowest—king, queen, and knave rank next in order, and then from ten downwards. The higher card of any suit takes the lower, unless the trick be trumped by a player unable to follow suit; and the tricks are gathered up by one of the pair, winning them, as made. Each trick over six taken in a hand by two partners counts one point to them towards the ten which makes game. The holding of "honours"—the ace and court cards of the trump suit—counts towards game, if a preponderance be held by either pair; that is, if the partners between them are dealt three honours, they score two points; and should they have all four they count four in respect of such holding. "Honours" counting before tricks, a pair of partners holding three or four, having reached a score of eight, may "call" them and win thereby without further play. It is usual for the holder of two honours at such a point to say to his partner, "Can you meet?" Should the answer be "Yes!" the cards are produced and the game triumphantly ended. When the "nine-hole" is reached, "honours" do not count with the players in that position. There are penalties for "revoking," *i.e.*, omitting to "follow suit" with a card of that suit in hand, and for other infringements of the elaborate rules of this scientific game, which requires playing with skill, deliberation, and perfect understanding between the partners. It is very engaging, and admits, consequently, of no general conversation. Dummy Whist (*q.v.*) is resorted to when four players are not available.

Zetema is a game following the principle of "Bézique" (*q.v.*); played, however, with a complete pack of cards and a fifth suit (either spades, clubs, hearts or diamonds) taken from a second similar pack and shuffled together amongst the four suits of the first, making 54 cards for use in all. Scoring is for combinations obtained and the tricks won, and special markers are requisite. These, with the rules of the game, are procurable at most of the toyshops.

Chequers or Checkers, an antique game similar to and the origin of **Draughts** (*q.v.*).

Chess. A highly scientific game of calculation, combination, and concentration, played in Britain now on a board divided into 64 squares, black and white alternately, with 16 pieces, or men, coloured black (or red) for one player and white for the other. These are differently carved, and represent for each, one king, one queen, two bishops, two knights, two castles or

rooks, and eight pawns. These have variant values, and the moving of each is regulated by strict rule, the object of the players being to checkmate the hostile king, which alone cannot be captured and taken from the board. Chess requires deep study, the problems possible, the theatres being of endless diversity and ingenuity. Personal teaching by an accomplished player is desirable.

Coddam is a curious game in which three persons seated at a narrow table manipulate in their hands, held together beneath it, a "piece" (dice or small stones being used) and then bring up the hands, closed smartly in a row, the "piece" being concealed in one. Three others, facing the first three, then have to guess, one of them touching the hand in which he or she considers the "piece" to be hidden. When this is found, the opposing trio take the "piece," and the first three become the guessers. Those making the least number of incorrect surmises win; and the play is accompanied by much facial distortion, badinage, and attempts to confuse the judgment. An incorrect guess is always followed by a disclosure of the "piece" from one of the other five hands, and a new disposition of it beneath the table.

Consequences. A parlous game, in which the players, seated at tables, write down, without collusion, parts of a brief imaginary social story on indicated lines; each folding down what they write and passing on the paper to the next contributor to continue the narrative, until the sheet, on unfolding, upon completion, contains the work of as many different writers as are playing. The characters introduced may be present in the company or not, as pre-arranged. Ten players are requisite for the following specification of the "Consequences" game, which may be ingeniously varied. First player writes:—An adjectival description of a lady; second, a lady's name; third sets down that the adjectival lady unknown met an adjectival—hardening the suitable description—gentleman; fourth the name of a gentleman; fifth, the meeting place of the two; sixth, when the meeting occurred; seventh, what the lady said to the gentleman; eighth, his reply; ninth, the Consequences; tenth, what the world said. The composite story might read at the conclusion thus:—(1) The gushing (2) widow Flighy (3) met sily (4) Lord Solthead (5) in the gloaming (6) guarding the shady lane (7) She said—"Kiss me quick, love" (8) He said—"Does your mother know you're out?" (9) The Consequence was—trouble for two (10) And the world said "Just what we expected." Good fun may be got out of this.

Court Tennis may be played in any large rectangular room or high-walled court, with a netting, three feet high in the centre, stretched centrally at a convenient distance from the walls, the pastime being similar in its main principles, to "Lawn Tennis" and "Racquet," described under "Outdoor Sports"; but highly technical as to detail of play and method of scoring when the "rigour of the game" is observed. The construction and marking out of a regulation court with roofed "pent-house," "dedans," galleries, "grille," "sanctuary," etc., is a matter for the expert, and scientific tennis-play can only be acquired by long practice under proper instruction.

Dabs (sometimes called "Jacks," "Jags," and "Knuckle-stones" or "Knuckle-bones") is a childish game—of very high antiquity—consisting of bouncing a round pot "Jack" marble on a hard stone, and picking up with the hand, or laying down, during the bounce, one, two, three, and then four square stones or knuckle-bones, separately and afterwards, together in different combinations, keeping up an audible count; the object being to continue as long as possible without failing to catch the "Jack" before the picking up or laying down operation is neatly accomplished.

Dances. Dancing, or the art of graceful foot movement with concurrent manual and bodily action, to the accompaniment and time of suitable music, particularly when in harmony with the motion of others, forms one of the most fascinating pastimes for the young of both sexes in this and every other country. Pursued under suitable social conditions, it may be as harmless as pleasurable. The quick and merry dance is most favoured by the sprightly in cool and spacious

assemblies; the slower and staller measure in warm climates and well-filled ball-rooms. We can only briefly glance at the more popular dances here. Their proper execution requires tuition. In the *Bouré Danse*, or *Pas de Quatre*, the partners keep together throughout. The *Caledonians* is a species of *Quadrille*. In five figures, ending with a grand promenade. The *Coltillon* is a combination of waltzing round, in couples and to partners, with the presentation of favours. **Country Dances** take the form of two rows of dancers, say twelve to fourteen couples, standing opposite. These dance in pairs "down the middle" and up again in turn; with other movements—varied in England, Scotland, and Ireland—according to the music. *Sir Roger de Coverley*, or *The Haymakers*, is a pretty country dance, with graceful bowing and curtsying interludes. *Galop* is a simple *dansé à deux temps*, quick and lively, in which the couples turn round as in the *Polka* and *Waltz*; it is adapted for the opening or conclusion of a ball. The *Gavotte*, now out of fashion, was a modified *Minuet* for one lady and one gentleman, with much advancing, retreating, and obsequious, slow and accelerated, to a lively air with repetitions. The *Mazurka* is animated and suitable for participation in by four or eight couples; at times joyous, at times grave, it comes of Polish origin. The *Polka-Mazurka*, resembling a slow *Polka*, is danced by single couples. The *Minuet*, danced to three time, is all elegance and graceful motion, with dignified curtsying glances, fitted for the grandest of costume balls. The *Polka*, of Bohemian extraction, is a dance *à quatre temps*, performed with spirit by separate couples. The *Polonaise*, also danced by separate couples, is the old national dance of Poland, wedded to music *à trois temps*, with peculiar syncopation and final falling cadence. *Quadrilles* are quiet and enjoyable dances, borrowed from France, engaged in properly by eight persons, the couples standing at the start on each side of a square. The *Lancers* is a particular favourite in this class. The *Redowa* is a round dance, slower than, but similar to, a *Polka*, and in some respects like a *Mazurka*, opening with positions as for a *Waltz*. It goes well after a *Galop*. *Reels* are of Scottish origin, brisk and picturesque, and may be danced by one couple or more in conjunction, to a quick measure, six squares, or four crochets in a bar. *Round Dances* are those performed by separate couples in progressive circular movement round the room, as distinguished from set square dances comprising complex figures. *Round Dances*, which are preferred by the majority, include the *Waltz*, *Polka*, *Schottische*, *Galop*, *Mazurka*, and *Redowa*. The *Saraband*, a Spanish dance, is sprightlier than, but not unlike, the *Minuet*. The *Schottische* was originally a German peasant dance, performed in couples, with glissade steps, springs, and double hops in the round movement. A *Spanish Dance*—distinct from the *Saraband*—is performed to slow *Waltz* music, with the *Falset* step, an even number of couples ranging in parallel lines, as in a *Country Dance*, at the start; dancing simultaneously down in the rearing, changing places, and executing other baroque movements in turn. The *Varvianina* is a repetition of gyrations, pauses, advances, and passes to right and left in *Polka* steps. The *Waltz* is a succession of graceful curves, with easy and graduated but undulatory and rhythmic action, reciprocal as between the partners, the swaying and gliding motion possessing much charm when triple time, in the requisite direction, to music in triple time. The varieties of all the dances referred to in vogue are numberless, some with novel introductions which lend them fleeting popularity, such as that accorded to the "go-as-you-please" *Washington Post*; others combining *Waltz* and *Polka* in a captivating way, as in the *Roundabout*. For general favour, as a square dance, the *Lancers* holds its own well, especially when executed with the flirtation figure "finale."

Dice are small white cubes, marked on the six sides with spots numbering from 1 to 6. One or more of these are shaken up in and cast from a wooden cup, the number of spots coming uppermost on the dice constituting the throw. Gamblers used to stake money on their hazards extensively, but in this country

dicing is now, fortunately, not favoured, either by public preference or common law.

Domineas. A game played by two or more persons with twenty-eight stones, or pieces of oblong bone, ivory, or wood, of uniform size, dyed black, faced in white, and dotted with black spots to indicate every possible numerical combination, from double-six to double-blank, a black central dividing line being marked from side to side of each. The game consists in matching and joining one end of the pieces played with one end of another held by the following player, those engaged playing alternately. In the simplest form of domino play, he whose hand of five or seven pieces is first played out wins the round; other games consist of a combination of this and the counting of all the fives and threes formed by the two ends of play to the score of the player who makes them. Each player not only endeavours to facilitate his own scoring, but to frustrate that of his adversary. When one has played his final piece, he is "domino." Some boxes of dominoes extend up to double-nine.

Draughts. A game played on a board made and marked as for chess (*q.v.*) with twelve black and twelve white discs or "men." One player takes the black "pieces," the other the "white," and places them on the three rows of white squares at his end of the board. In turn each moves a "piece" forward, diagonally, either to left or right, one square at a time, keeping to the white squares only, the object being to capture or hem in the "pieces" of his opponent. Any "piece" advanced to the further row on the antagonistic side of the board becomes a "king," and must be "crowned," when it may be moved by the player backward as well as forward. A "piece" left after a move capturable by an adversary must be taken by the latter, or he is "huffed," *i.e.*, he loses the "piece." Capture is effected by leaping over an opposing "man," or to a vacant white square beyond, upon the line of march, from the white space immediately in front; but no player can advance by skipping across one of his own "pieces." A continuous series of leaps may be made at one movement, should blank squares admit. Crowning consists of the placing of a surrendered "piece" upon the "man" which has become a king. He who remains in possession of one or more pieces, crowned or uncrowned, upon any but white squares when his opponent's score is exhausted, wins the game.

Dumb-bells. The manipulation of these, of suitable weight, and of the longer separated allied "Bar Bells," with moderation and regularity, is at once a useful exercise and an agreeable pastime, calculated to keep the muscles in condition.

Dutch Pins is a form of alley-ball game akin to "skittles," consisting of the knocking down, in a few throws as possible, from a marked distance, of wooden "pins" placed in position upon a frame. The missile is usually cheese-shaped, lighter than that employed at "skittles," as also are the "pins," nine in number.

Fencing, with "foils"—not much needed, nowadays, as a protective accomplishment—may be practised advantageously as a pastime and a physical exercise, under competent tuition, by either sex, inasmuch as it does, supplemen of limb, quickness of eye, and muscular strength.

Five Stones. Another name for the marble and square stones bouncing game "**Dabs**" (*q.v.*).

Forfeits are an amusing feature of many pleasant parlour pastimes, some little article, such as a handkerchief, being deposited by the player failing to accomplish a set task—as in guessing games—or committing a breach of rule, to be redeemed by the performance of a penalty at once as harmless and comical as possible, imposed by the company. To blow out a candle whilst blindfold is an amusing example of forfeit.

Go-Bang may be played on an ordinary Chess or Draught-board, the object being to get five "men" in a row, straight or diagonal, with no unoccupied space or "piece" belonging to an opponent intervening. One plays white, the other black, and eight or more "men" can be used by each player; these being placed one at a time in the endeavour to attain the desired combination, or balk the opponent. When both sets

of "men" are down before either player has got his five row, each may move any "men" of his own alternately one space, whenever there is a vacancy; the player who first places his straight uninterrupted five wins. The Japanese play this game on a board of small squares, in numbers, with anything up to 264 counters apiece. Three players with 108 "pieces" each, or four having severally 84 "men" at command, coloured distinctively, may take part in the extended **Go-Bang**.

Guessing Games for the parlour and children's parties may consist of conundrums, charades, or other similar exercises of the wits, the correct guesser becoming interrogator. Or there may be attempts to identify fellow-guests, when there is a large assembly, by the eyes or hands alone; in the former case two or three persons being seated at a table, concealing them below waist, with newspapers enveloping their heads and shoulders, silts being cut to show only the eyes; and in the latter the hands being extended over a screen for inspection. Identification is more difficult than might be imagined, and forfeits can be amusingly imposed for wrong guessing.

Gymnastics, contemporaneously with intellectual culture, provide commendable pastime and beneficial exercise. Gymnastic games develop and keep the muscles in trim, whether practised with or without apparatus; and, provided that the gymnast be airy and properly appointed, and that the incentive of competitive endeavour does not induce the overtaking of the strength, suitable exercises should be regularly gone through by the young of both sexes. Kings, wands, Indian clubs, dumb-bells, bar-bells, etc., may be beneficially employed; parallel bars, horizontal bars, the swinging trapeze, the vaulting horse practised upon; fencing and all manner of physical exercises and indoor games calling for the exhibition of strength and dexterity, including jumping, bending, climbing, or stretching, separately and in combination, contribute to the upkeep of mental vigour as well as physical elasticity and soundness.

Halma is one of many simple games with boards and movable "men," for parlour pastime, needing no description, the rules for its playing being supplied with the requisites procurable at any toy bazaar.

Hand Rings, attached to suspended ropes, form part of the fitness of most gymnasia, and are very useful in body raising and arm-muscle exercise.

Hunting the Slipper, like **Catching the Ring**, is a simple and diverting game; all the players being seated in a semicircle on the carpet save the person left out to hunt. The slipper is passed about surreptitiously and dexterously betwixt, under, or behind the seated players, and on being located, the one in whose possession the objective is detected has to take up the hunt, and, if agreed beforehand, pay forfeit also. In **Catching the Ring** a string is loosely extended between the hands of those at the ends of the half-circle, and moved back and forward by any of the players to elude the would-be catcher.

Indian Clubs are of various weights, for swinging and manipulation in gymnastic and physical drill, and may be used to suit harmonious exercise.

La Brosse, or The Brush, has affinity to "Hunt the Slipper," except that the players stand in a complete ring, holding on with their right hands to a cord extended before them, and passing about a small hand brush with the left. Dancing around and singing or humming a merry tune, if possible to piano accompaniment, they trust the brush to one another as smartly as possible, audibly brushing their neighbour's clothing therewith before losing hold thereon; the object being to confuse the searcher, who stands within the whirling ring. His or her back may be audaciously brushed when his search is wrongfully directed, *la Brosse* being immediately passed away or even thrown across the ring at the risk of being caught by its seeker, who is out of the game making a capture, the one from whom the brush is taken becoming searcher, to the shortening of the circle. When only four remain in the game the ring becomes too small for free motion, and the game ends, or begins over again.

Lotto is a parlour game with numbered discs and cards, one player having the discs in a bag and casting

them out rapidly on to the table, "calling" each number aloud. The other players pick these up as quickly as they can and deposit them on correspondingly numbered spaces upon the cards dealt to them before the disc distribution begins, the one first covering his or her cards completely and properly winning. There are twenty-four cards each having fifteen distinct numbers, ranging from one to ninety, so that each number is repeated in the pack four times; and the complete stock of discs will cover all the spaces. Two, three, four, six, eight, or twelve players may hold cards, distributed to them in equal number. "Picture Lotto" and "Natural History Lotto" are variations from the numerical game, designs taking the place of the figures on the reception cards and playing discs or squares, as the case may be. Quick eyes and hands are wanted when the "calling" is dispensed with, as is usual in pictorial "Lotto."

Morrice, Nine Men. An old game played on a chequer-board, similar to the modern chess-board. Each player had nine "men," differently coloured from those of his opponent. These were placed on the angles of the squares, alternately by each player, and then moved as draughts. Every time each player got three of his own "men" into an uninterrupted straight linear position, he removed any one of his adversary's "pieces" he might choose from the board, until one player lost all his "men" and the game.

Nine Pins. A toy game of skittles (which see also **Push Pins**), the inside in this case being a light wooden sphere, and the pins turned with neck and head. Made in various sizes and available for use on floor or table.

Ping-Pong is a species of "table tennis" for parlour play, with very light, small, hollow, celluloid balls, drum-battledores, and a dwarf driving net; the game being to keep up continuous striking—always over the net and on the table—as long as possible, and to give awkward returns which will force the adversary to yield "faults," each of which scores towards game for his or her opponent. The players serve in turn.

Punching the Bag is a variation of "Ball Punching" (q.v.), a slung stuffed bag being substituted for the inflated ball used in the latter exercise.

Puppet Shows and mimic dramatic performances of the "gallant" show order, in which figures were made to dance and move about with strings and wires, are obsolete; and marionettes, unless of an elaborate character, have ceased to charm the children of this exacting generation of many available entertainments. Only the perennial "Punch and Judy" show holds its own at all, and even that has to be particularly well presented to prove acceptable.

Push Penny (or "Shove Ha'penny") was the propulsion of a coin laid flat to positions marked diagrammatically on a deal table, by striking, with the palm of the hand, its edge with the penny projected over the end of a table. It was a poor game, with sordid associations, and is now all but forgotten.

Puzzles, of the dissection and mechanical order belonging to toydom; arithmetical and geometrical problems of a complex and confusing character afford mental exercise to the ingenious and inculcate perseverance, so ranking as pastimes. But they cannot properly be regarded as games.

Race Games. These and many other ingenious box-games are usually fully described and explained by the manufacturers. Their name is legion and their variety unending.

Roller Skating on indoor rinks is but a poor substitute for the exhilaration of ice-skating in the open on blades of steel, but it affords exercise when the preferable pastime is out of question, and should therefore here receive mention.

Rope Quiffs may be used indoors as well as on ship-board. Their lightness makes them manipulable by the fair sex, and they afford exercise mingled with entertainment.

Roulette is an interdicted gambling pastime, played at special tables, on highly speculative lines. Huge sums in the aggregate have been lost thereat in Continental towns.

Round Games at cards are those in which each player acts independently instead of in partnership with another, as Loo, Brag, Matrimony, Pope Joan, etc. (See Cards.)

Scandal. This is a rather dull game, in which the company sits round, and the first of the party whoport a brief personal story—not necessarily concerning anyone present—to his or her left-hand neighbour. It is repeated all along the line in an undertone, and having reached the last person, the ultimate version is compared with the original, when it will usually be found to have become considerably variant.

Shadow Buff. A white sheet is suspended towards the end of the room; before and facing it a person sits, on the carpet or a low stool. At the opposite end of the room a lighted lamp is placed, all other lights being removed or extinguished. Then, in turn, the rest of the company pass well behind the seated person and between him or her and the light, temporarily disguising gait or dress. From the shadow cast on the sheet the guesser endeavours to divine who occasions it. Upon detection, the person pays forfeit and becomes the guesser. With a little ingenuity "Shadow Buff" may be very diverting.

Singletick is a description of fencing (*q.v.*), and formerly denoted a kind of cudgel play, in which the contestants set about each other lustily until one drew blood from the other's head, and was declared the victor.

Skittles is played in an alley, long and narrow, with nine heavy wooden pins placed on end upon a frame in diamond position, one point of which fronts the player, whose missile is a heavy flattened "cheese" of hard wood. His object is to knock down the whole nine skittles in as few casts as possible, and an expert, with a very fortunate throw, may floor the whole nine at a throw. In "Dutch Pins" (*q.v.*) skittles and cheese are less weighty than those used for the regulation game, and the centre one, called the "king," is the taller of the nine. In one form of skittles, the ball (in that case round) is suspended by a cord from the ceiling at a height just sufficient, when swung skillfully, to strike down any ball it may hit.

Snadragon is a merry game of considerable antiquity—associated with Christmas gatherings—in which raisins saturated with flaming spirit are snatched from a dish in a darkened room, and placed into the mouth immediately.

Solitaire is played on a round board with thirty-three holes on its upper surface. In each hole is placed a glass marble. The player takes away any one marble, and moves thence to any other separated by one from the vacant hole, removing the marble skipped over from the board, as with "men" at draughts; the object being so to take all but one, leaving that the hole rendered vacant by the first move.

Spellicans (or **Spillikins**) is a modern adaptation of the old English game of "push-pin," or "put-pin," played nowadays by children chiefly and elderly folk, with a number of short "spells" or "spills" of wood, bone, or ivory, procurable in boxes at most of the big toyshops. It provides a mild parlour diversion for two persons, at a board or table, and admits of some dexterity of hand without calling for any exacting exertion.

Swimming (referred to under "Outdoor Sports") may conveniently be mastered and indulged in at properly appointed baths, under cover, which are also suited to the display of one's swimming and diving, both very useful arts and invigorating pastimes, when rationally engaged in.

Tableaux Vivants consists of the arrangement of groups of persons in character—to represent some scene in history or romance—with illuminative accessories, the subject being left to be divined by the company. Unlike "Acting Characters" and "Proverbs" (*q.v.*) the characters do not speak; nor is action essential, though that may be permissible if the

stiff and limited movement of the automaton be imitated by the subject, after a preliminary suppositious "winding-up" on the part of the showman, as in "Mrs. Jerley's Wax Works." *Tableaux Vivants* proper, and the latter corollary thereof, affords scope for effective dressing and stage management, and may be made very interesting and amusing.

Tennis. (See Court Tennis, also Lawn Tennis in Outdoor Sports section.)

Tiddley Winks is played by any number of persons at a cloth-covered table, with small thin discs of coloured bone. These, by deft pressure towards the edge with a larger disc, are caused to spring towards or into a wooden cup placed in the centre of the table. Each player starts with an equal number of discs, coloured differently from those of his fellow players, ranging them in line at the edge of the table in front of him. Shots towards the cup are taken in turn, and when a disc is landed therein the player continues until a miss is made by him, when the next player proceeds. Whoever first cups all his discs wins. One disc springing upon another, the under disc cannot be played until that super-imposed has been shot away by its owner in his proper turn. Either sex, young or old, may play, and celerity is quickly acquired by practice.

"Tip It" resembles **Coddam** (*q.v.*), the guessing player, on demanding disclosure of any hand when he believes himself to have located the "piece," crying "Tip It!"—"from the left" or "from the right"—as the case may be.

Toys, simple or mechanical, are the desire and the joy of all children; and often the most simple give the greatest joy. There are, however, toys to suit every childish fancy, procurable at prices within reach of all pockets. Those which belong to elaborate games and display complicated detail requiring costly material, are for the more favoured juveniles of course; but no child need in this age of indolence and ingenuity, lack a sufficient paraphernalia of play.

Yaulking, whether with the high, low, long, or short horse, or with the parallel bars, is a pastime belonging to gymnastic practice. It assists and lends variety to leaping exercise.

Wand Exercises, with smooth sticks about an inch in diameter, and three to four feet long, for grasping with both hands, are beneficial in giving flexibility and strength to the muscles of the shoulders and neck. (See **Calisthenics** and **Gymnastics**.)

Wibbly-Wob is a species of parlour ball game, played on a table, with a small ball and wooden-headed and handled flexible wire wands, the object being to get the ball into a goal receptacle at opposite ends of the table, players thrusting at the ball in opposition pairs.

"**Wills**" is a round parlour game, in which the players write down on a sheet of paper, ruled into spaces, a given number of persons or institutions to which he or she would bequeath property. What is written is folded under, longitudinally, and the paper passed to the next player, on the left, each receiving that of the player on the right. Then in spaces in line with those folded under is entered by each the legacies or articles to be bequeathed to the correspondingly nominated beneficiaries, who are of course unknown to the writer. The papers are folded and passed again, and a third correspondent entry made indicating what it is supposed was done with the bequest by its recipient. At the conclusion, the papers are shuffled from hand to hand, and then read out, when some such result will be disclosed as that the willmaker left to (1) "His Relict," (2) "A Cork-screw," and (3) the legatee "Stewed it till Tender"; or (1) to "The Home for Lost Dogs," (2) "My Dress Suit," (3) when the receiver "Wore it next the Heart"; or, again to (1) "My old Sweetheart," (2) "A Shower-bath," it being (3) "Reserved for a Rainy Day." Council combinations, relevant or irrelevant, when the "Wills" are read, make great fun.

PEARS'
of
DICTIONARY
THE TOILET.

EDITED BY
LENA GUILBERT FORD.
Toilet Editress of "Madame" and "The Lady's World,"

Pears' Dictionary of the Toilet

INTRODUCTION.

By LENA GUILBERT FORD,

Toilet Editress of "Madame" and "The Lady's World."

Every self-respecting woman wishes to look as well as she can, and what a delightful place this old world of ours would be if every woman were a thing of grace and beauty! To attain a considerable share of beauty is not nearly so difficult a matter as might at first sight appear, though beauty in its higher forms—the beauty which poets rave about and which is so generally captivating—is a gift which nature takes care not to make too common. It is gratifying to know, however, that by care and culture every woman has it in her power to greatly improve her personal appearance, and add to the charm of her features.

The beauty to which I refer is not the mere superficial attraction whose power is necessarily evanescent, but represents that far-reaching self-culture which accentuates the best lines of the "human form divine" and improves the weaker points—which, in short, amounts to a general cultivation of personal radiance, and a study of those minute details of the toilet which are real "aids to beauty."

Within certain well-defined limits, art—that is, toilet art—can achieve a great deal towards enhancing a person's good looks, and can often make "plain" people attractive, for there are always improved effects to be obtained by "toning up" here or "toning down" there—effects which even the most favoured of natural beauties cannot afford to neglect or despise.

What is known as beauty-culture is really only another name for health-culture. The two ought never to be separated, for what is detrimental to health must also be detrimental to beauty; and it should never be forgotten that it is with the skin that you have to deal first and foremost in promoting beauty. The receiving old adage that says "beauty is but skin deep," has done a lot of harm. It has confused in thoughtless minds the vice of vanity with the virtue of self-respect. Skin-deep is deep enough, for when the skin is truly beautiful there can be nothing much wrong with the effect of the features. No woman can fail to make a good impression if she be blessed with a fine complexion.

"You cannot improve upon nature" is another proverbial snare. As well say we should leave the vine or the rose-tree to grow in its own wild way. Where there is the best natural environment this leaving nature alone may be wise, but we seldom meet Mrs. Nature in her primitive state nowadays. She is swayed and moulded by the force of changing circumstances and conditions, and a guiding touch of the human hand is often most advantageous. Our physical beauty is amenable to all sorts of improvement, and even the actual shape of one's features may be modified to some extent by judicious treatment.

In the ensuing pages care has been taken not to trespass beyond the legitimate limit within which nature will respond, for to attempt to leave nature behind in these matters is to court humiliating failure. Toilet requisites, I must add, should be few, simple, and good, but the keynote of success in these things is complete and perfect personal cleanliness. A careful study of the instructions here laid down, however, cannot fail to yield gratifying results.

LENA GUILBERT FORD.

On subsequent pages are presented in alphabetical order a number of hints and observations covering in a practical manner the various matters connected with the Toilet. These hints represent a long and wide experience and will be of assistance—especially to our lady patrons—in laying down certain valuable rules by which the most can be made of one's personal charms, particularly if taken in connection with the more general information given in another section of this work, viz., "Pears' Dictionary of Health."

Accessories, Toilet. The paramount requisite of the toilet is a sufficiency of good soft water, naturally so, or made so by some of the many softeners at a temperature suited to the immediate purpose. Next in importance is the supply of pure soap prepared from the best detergent material in an expert and scientific manner, and free from an excess of alkaline substances. (See *Soap*.) There should be accommodation for the bathing of the entire body, or for the ablation of any part thereof, as may be required, such accommodation being as simple and yet as convenient and complete as possible. In the bathroom every appliance should be maintained scrupulously clean and orderly; and the same remark applies with equal force to the dressing-room and the toilet table. Tidiness in these things conduces to the cult of beauty and the promotion of health and personal comfort. Obtain and keep in constant working condition everything really wanted for attaining these objects, according to your individual needs and means; and do not "number up" your dressing-room with useless things. Have a well-considered place for each article, and never let the article be out of that place except when in use. See that the mirrors on wardrobe, dressing-chest, and elsewhere are situated in the best positions as to light and availability; keep the hand-glasses convenient and safe, and have the brushes, combs, sponges, towels, and other articles of toilet service arranged suitably for ready use. A rational and systematic provision of this kind will save much trouble, and enable you to perform the operations of the toilet with satisfaction and success. For the rest, the paragraphs which follow will be found helpful as to detail.

Acne. The ugly spots or pimples which frequently appear on the face—especially of young people—is a disease of the skin glands, and when it takes the form of what is called "blackheads" detracts considerably from the beauty of the skin. It is a common practice to force "blackheads" out by pressure of the fingers, but this is not only painful but leaves a swelling which sometimes develops into a hard and permanent lump. An excellent lotion for getting rid of these things is made as follows: Flowers of sulphur, one teaspoonful; rose-water, one pint; glycerine, one teaspoonful. But when the spots are obstinate the following preparation will be found effective: liquid ammonia, twenty drops; ether, one drachm; Pears' Soap, one ounce. Bathe the affected places with hot water, rub in a little of this mixture with the thumb, and wash it off with hot water. Persons subject to acne should avoid tea and coffee, and use cocoa or warm milk instead. They should not eat pastry, sauces, cheese, or any highly-seasoned dishes, but eat freely of fruit, tomatoes, and well-cooked green vegetables. At night the face should be washed in hot water and steamed well, afterwards rubbing a little eau de Cologne into the skin. Ordinary face powders should be shunned, but Pears' Violet Powder is at once soothing and protective.

Age, Old. Persons of advancing years, if wise, will accept the inevitable changes of time with a good grace, and not endeavour to appear dress, or adorn themselves in a way more fitted to their earlier years. To ape juvenility in life's decline is to draw pointed attention to the actualities which cannot be concealed. Careful living, and the preservation of good temper, with regular exercise suited to the strength, in pure air, are age's best cosmetics. The toilet of those past their meridian should aim at preservation, not an impossible restoration or ridiculous dissimulation. Rigorous cleanliness, inconspicuous attire, and neatness, go a long way towards arresting a too speedy advance of the marks of age. It is natural to dread the little souvenirs which Father Time leaves with us on his yearly visits. In many instances we may outwit him, and since the art of beauty-culture has reached so high a degree of perfection, we feel comparatively few "elderly" women. It is a charming thing, we are told, to grow old gracefully, but most of us prefer to keep young gracefully, and one of the first things to watch for is the appearance of the neck. That is the tell-tale age-mark for most women, notwithstanding their remarkably young faces. The flesh on the neck gets "strungy," and when the head is turned the

unpleasant secret is out! Exercises for keeping the neck in form are simple. An effective one is to stand with the hands on the hips. Inhale a deep breath, force it against the sides of the throat, and hold it for five seconds; then exhale slowly through the mouth in whistling position. If a lighted candle is held before the hips, the breath on departing from the mouth should not waver the flame. It requires much practice before this is possible, and giddiness is liable to ensue during the first attempts. Then, while the neck is thus inflated and the "salt-cellsars" have disappeared, the head is turned slowly from side to side and from front to back. The good effect is seen instantly, but of course is not lasting to that extent, although some part of the benefit remains after each exercise. Another sign of approaching old age is the short nervous step. Therefore anything that will keep the joints well oiled, and the step light and springy, does something toward retaining the youthful appearance. The round shoulder is suggestive of passing youth, and women who sit much during the day to write, read, or for other purposes, must be particularly careful. After sitting for a long time it is a good plan, and wonderfully refreshing, to extend the arms in front of the body, placing the palms of the hands together. Lift them slowly over the head and bring them down at the back, separated, always having the feeling of making the hands as nearly as possible at the centre of the back. Inhale as the arms go upwards and rise on the toes; exhale as the arms descend and regain normal position of feet.

Arms, The. Arms of perfect proportion are uncommon. They are often either too fat or too thin, especially from the elbow to the wrist. In either case massage is the best means of improving them. The flesh of one arm should be firmly grasped with the hand of the other and worked steadily up and down with twisting movement for ten minutes. Then the other should be similarly treated. The development of the arms will be much assisted by dumb-bell exercise, which brings the muscles well into play. Such exercises, however, should be indulged in with moderation, or harmful fatigue will be caused, and the bells should be a pound in weight. Ten minutes is ample for a beginner, but as the muscles become more used to the proceeding they may be gradually extended. Should the skin on the upper arm be toughened and red, the occasional and very careful use of a piece of pumice stone and a small quantity of lemon juice diluted with water will quickly render the skin smooth and white. The arms ought always to be protected from the weather. When exposure to the air is unavoidable a good coating of cold cream, well rubbed in and powdered with pulverised oatmeal, will prevent the coarsening of the skin. The fashion of short sleeves which prevailed for several seasons revealed a sad story as to the shape of fore-arms in general. The shape of a well-developed arm between the elbow and the wrist is exquisite and it is quite easily obtained, and always can be improved. If the arm is too thin, a good exercise is to extend the arms, clench the hands and slowly lift the hands up and down, bending at the wrist. The feeling of resistance should be given all the time to the muscles and the strain will be felt along the fore-arm. This should be done five minutes as many times a day as convenient and a difference in the plumpness will be noticed in a short time. Then a good skin-food should be rubbed well into the arms at night. Olive oil will produce no results in this direction, but in using olive oil it must always be borne in mind that it darkens the skin. It is wiser when applying it to the face, neck or arms, to use a cream whose basis is pure olive oil. In the morning the arms should be bathed first in warm water and then in cold, then in warm again and finishing with cold. The friction should not be strong in drying, but if the arm is not wiped thoroughly dry, the skin will become coarse and rough. It is seldom that the arm is too fat, but if such is the case, the superfluous flesh can be removed by taking it in rolls between the first finger and thumb, and rolling it gently. The massage rollers for this and similar purposes are effective. Tapping the arms with the flat of the fingers moistened with cream will also

increase their plumpness, but during all these treatments, the wrist must be properly exercised in order to keep it slender. Dimples in the elbow are considered a mark of beauty, and nothing is more hideous than a sharply pointed elbow. The point should be treated by soaking in hot water for twenty minutes a day and then massaging gently.

Baldness. There are many vaunted specifics for the prevention and cure of baldness; but none less harmful or likelier to afford general satisfaction than the following cheap and simple application:—Whisk up the yolk of one fresh egg, and mix therewith an equal quantity of the squeezed and strained juice of chopped and uncooked Spanish onions. Add thereto as much crude cod-liver oil in quantity as the two foregoing ingredients make together, and then whisk the whole for fully five minutes. The resulting ointment may be perfumed to mask its rather disagreeable odour, placed in a tight receptacle, and a little rubbed into the scalp patiently every night, after first bathing the part well with warm water. This application will not, of course, be efficacious, if what are commonly called the hair "roots" are decayed from natural causes; nor, for the matter of that, will anything else.

Baths and Bathing. The cold plunge bath is a capital daily invigorator for the robust. For cleansing purposes, and the preservation of health, water heated so as to approach nearly the normal bodily temperature is best; and the room in which the bath is taken should be efficiently ventilated. The water employed ought either to be naturally so, or so rendered by the addition of ammonia, borax, oatmeal, bran, or other suitable agent. The most important aid to the bath, however, is a pure, wholesome soap, especially prepared for the skin, and capable of thoroughly cleansing, and, at the same time, possessing those emollient, softening, and preservative properties, which directly conduce to the health and beauty of the skin. Pears' Soap is such a soap. It has been the leading soap for the bath and toilet for over a century, and is pronounced by the most eminent scientific authorities to be unsurpassable. This matter of the right soap is the most vital consideration in the entire economy of bathing, whether as regards the whole body at once or otherwise. After leaving the bath, the risk of chill must be adequately guarded against. Care, brisk towelling, and quick dressing will ordinarily suffice. So much for the usual home bath. Turkish, vapour, or medicated baths for special purposes should be taken under proper directions and supervision.

A delightful variation from the every-day ablution may be provided by the use of a bath sacket. Get a sufficiency of soft white towelling, and make ~~one~~ bags, about four inches by six inches in size, leaving one side open. Then prepare the following mixture, and fill the bags with it, until they are, when laid flat on your hand, about half an inch thick:—Powdered borax, four tablespoonfuls; powdered orris-root, three tablespoonfuls; Pears' Soap, finely shaved, four tablespoonfuls; good smooth, fresh oatmeal, four large teaspoonfuls; oil of lavender, ten drops. Sew up the bags, and in the morning let one soak in the bath water for ten minutes, then use it as a washing glove until the whole of the body is well lathered. Then proceed with the bath, taking care ultimately to rinse off the whole of the lather.

Bath, Beauty. A beauty bath, of especial benefit to those who suffer from a dull, sallow skin, is ordered as follows: If possible use rain-water of comfortable temperature for this bath, or, failing that, warm water from the tap, softened with borax. Then bring into use a specially prepared bath lotion made as follows: four ounces of rosewater, to which must be added one ounce of glycerine, a teaspoonful of powdered borax, one ounce of alcohol, one ounce of tincture of benzoin. Before being used this mixture should be allowed to stand about a week, being occasionally shaken to secure the proper mingling of the ingredients. At the end of that time two ounces of rosewater should be added.

Bath, Sea Salt. This has now been made a simple matter, sea-salt being easily obtained for a few pence a bag from any chemist, and a cupful of seawater into the bath is all that is required. But the exhilarating effects gained by bathing in the sea are to a great

extent absent when the sea-bath has to be taken in one's own room.

Bath, German Spa Method. A form of bath given by many of the German Spas can easily be carried out in every detail in any ordinary bath-room. Take a pint of good table-salt and spread it over the bottom of the bath, and add a little powdered borax. Fill the bath with boiling water and allow it to cool to a tepid temperature. Take a quick scrub in this, allowing the water to dry the skin. A second bath in clear warm water should be taken after this, using Pears' soap for its special soothing qualities. No matter where the salt bath is taken, whether in the sea or at home, it should be followed as quickly as possible by a clear water one, as indicated, for although salt water is invigorating to the muscles and good for the general health, it has a very injurious effect upon the complexion.

Beauty, The "Cult" of. Intelligent and faithful observance of the hygienic laws pertaining to our systems, and the wearing of apparel fitted to the seasons and to our individual requirements, lie at the very root of the "cult" of beauty, which is attainable by all who are endowed with shapely forms and comely features, or who by the various means at hand, will cultivate them. Indeed, there is much to be done to remedy nature's shortcomings in this respect, by the exercise of proper measures. The first consideration is health, for, lacking that, the human form is bereft of its natural bloom and freshness, and the signs of decay set in early. One of the great essentials of health is the maintenance of the various functional operations in a condition of natural activity, which applies not only to the chief organs of secretion, but to the proper action of the pores of the skin, for which good soap and water are the first aids. Our living should be regulated, day and night, to the harmonious realisation of "joy and temperance and repose." Caprice and indulgence set their detracting marks on personal beauty, and cannot be allowed to dominate "the deeds, done in the body" with impunity. Diet, exercise, and regular living (all of which matters are here dealt with under separate headings) are ruling factors in both health and beauty. The observance of the toilet must be looked upon as a sacred duty by all who wish to attain or maintain beauty, the primal duty being to keep in perfect cleanliness "the casket which enshrines the soul." This is the great guiding principle of the "cult" of beauty, to be applied in a common-sense way, by legitimate means, incessantly. Much can be done by persistence.

"Beauty" Foods. (See Diet, Complexion, and Acne.)

Blackheads. (See Acne.)

Boots and Shoes. (See Feet.)

Breathing Exercises. The disagreeable "colds" which affect young and old alike during the winter months would be almost unheard of if everyone indulged in a regular course of breathing exercises, a few minutes at a time, in the morning, and once during the day, either out of doors or before an open window, devoted to correct breathing should, in a very short time, work a wonderful change for the better in an anæmic person. A girl or woman before commencing to exercise should loosen the corset and all belts and bands that are at all tight; the window must be wide open, if the exercise is performed indoors, and the patient essaying the deep-breathing "cure" must stand facing it and take deep breaths. These must be drawn in slowly and steadily through the nose, until the chest rises and the lungs feel as full as they can comfortably be. The breath should be held for at least two seconds, and then forcibly expelled through the mouth. After the lungs have been completely emptied, a few seconds' pause should be allowed before the process is repeated. Very delicate girls may find this exercise rather exhausting at first, and should be allowed to lie down in the early stages of the "cure," say, upon a rug on the grass in summer, or on the floor in winter, before the open window, with a rug pushed up to the door to prevent draught. Very weakly people, especially those whose hearts are all affected, should fill the lungs by short breaths at the beginning, and as the lungs gain

strength by the exercise the breathing can be lengthened without fatigue. "Health and quiet breathing," to use Keats's expression, are amongst beauty's most precious secrets.

Breath-Sweeteners. One of the best, whatever be the cause of the objectionable exhalation, is a mixture of powdered, prepared charcoal, cinchona bark, cream of tartar, and attar of roses, which will be made up in the relative quantities requisite by any reliable chemist at a moderate cost. Eau de Cologne of good quality, diluted with filtered water, is a simple and useful mouth-wash, and to this a little tincture of myrrh may be advantageously added. Even simpler and cheaper is a solution of borax and water, with honey of roses incorporated. For smokers, liquid chlorinated soda with distilled water, in the proportion of one to twenty, is capital; and a drop or two of orange flower essence may be introduced for odorous effect. Cloves and other powerful aromatics, such as peppermint and cinnamon, rather defeat their object by their assertiveness. (See also **Perfumes**.)

Bust, The. An over-sumptuous bust can be placed less *in evidence* by skillful dressmaking, as can also an unduly flat chest; while both may often be permanently improved by judicious and persistent exercise. (See **Costume**, **Choice of**, and **Exercises**.)

Carriage. There is no one thing which helps more toward the possession of "personal charm" than does a good carriage. The importance of a fine carriage and a graceful walk can scarcely be over-estimated. First of all, to obtain a good carriage, one should stand erect, the weight resting on the ball of the foot, and the heels only just gently touching the floor. The abdomen should be drawn inward as far as possible, and at the same time the chest is raised. With an amateur, the chest can still be forced higher by drawing a deep breath, and by muscular effort the chest may be made to expand an inch or so. The elbows should be drawn backward and slightly bent, and the shoulder-blades should have a feeling of meeting at the back. When this is done, a book is placed on the top of the head, and if the neck is in correct position, and the head properly poised, the book will not fall in walking. The Grecian ladies of old, who were famous for their graceful carriage, swayed the head slightly with each step, but this movement will come naturally, if the other points are mastered in turn. It is difficult to explain in words the exact process of learning to walk correctly, and at first there is bound to be considerable stiffness in the movements, but an easy swinging gait is bound to arrive if the above instructions are carried out in front of a mirror. The shoulders must not move noticeably, but from the waist downward each part of the body has its work to do. The hip moves forward as the right foot is extended, and the movement of the knee is not simply to push forward, but as a marked prancing of a horse it lifts the foot from the ground, performing a rotary motion, and when the foot meets the ground again, the heel should point to the instep of the other foot. If the step is taken in this fashion, there will be no wearing down of heels, in the wrong place or no running over of the foot.

Chafing. For chafing, oxide of zinc ointment is good, but a better and a sure remedy for all ordinary cases—and a sure preventive of chafing if regularly used—is Pears' Precipitated Fuller's Earth.

Chapped Hands. (See **Hands**.)

Cheeks, Hollow. A good plan when the cheeks become noticeably hollow is to wet them with cold water, and while wet rub with a soft curly towel round and round in the sunken places very lightly, so as to affect the muscles beneath the skin. It will bring fresh blood to feed the muscles, and will strengthen and render them firmer. This simple attention will often cause the sunken cheeks to fill out. (See also **Face**.)

Chilblains are very troublesome in winter to many people, and when on the hands are unsightly. The following solution, if adopted in the earlier stages, will generally effect a permanent cure: Put three grains of sulphate of copper to an ounce of water, while equal parts of soap liniment and belladonna will help to

allay the irritation. Another efficacious and simple remedy is this: Take a piece of alum about the size of a walnut and melt it in a pint of hot water. Soak the hands in the liquid before going to bed for ten or twelve minutes, after which they should be covered with gloves without grease of any kind. In the morning the hands should be soaked in a solution made of half a pint of rosewater, three drachms of sulphuric acid, and the same quantity of myrrh.

Chin, Double. There are three corrective courses open to one threatened with the undesirable adiposity known as "double chin." The first is massage, which in this instance consists in gently pinching and kneading the flesh by holding it firmly and rolling in the fingers, and then smoothing it back. This treatment must be steadily persevered in if it is to be beneficial. A second method is directed to reducing the amount of flesh beneath the chin by means of bands of plaster to keep the suppurous flesh in position. These bandages should be worn every night, and although they are by no means comfortable, constitute a reliable remedy. The bandage must be placed under the chin, and passed over the ears by the crown of the head. It is always advisable to have an additional strap passed from the outer edge of the bandage to the back of the head. They may be made of the ordinary bandaging strips or of a good elastic. In the latter case care has to be taken that they are not drawn too tight, so as to interfere with the circulation. The third, and perhaps the most certain remedy for "double chin," is a regular course of exercises. Begin by throwing the head backwards and upwards, at the same time keeping the lower jaw thrust out. The teeth should then be clenched, and the muscles of the throat drawn upward and relaxed, and then drawn up again. Turning the head from side to side to the fullest angle of which it is capable should be the next exercise. If these exercises are indulged in for about ten minutes a day there would be a very marked improvement in the condition of the chin in the course of a few weeks.

Chiroprody. (See **Corn**.)

Clothes, Care of. Never put clothes away unclean, and never forget to pull and straighten the gloves, to roll up veils carefully, and never sit about in a walking-dress indoors, are golden rules to remember for the preservation of raiment. The "well groomed" appearance for which every wise woman strives, is due as much to the care of the clothes when not being worn, as to the clothes themselves. Generally speaking it is better to fold than to hang clothes, but the correct folding of one's wardrobe is a study by itself. Bodices should be held by the top of the sleeves, the yokes allowed to droop down and the back folded in. This brings the two front pieces lying one over the other, where they can be laid without creases. If it is necessary to fold again, the sleeves may be doubled across, but it should never be difficult to find cardboard boxes large enough to take the blouse folded only lengthwise. Several blouses can be put in the same box if folded in this way, and skirts are better laid in drawers than hung in closets unless stretched on frames. The woman who strives to be thought well dressed will have innumerable boxes, containing belts only, gloves only, etc., and labelled. The way to fold a skirt with a train is to lay it on a bed or table, folded down the middle of the front. To begin the train, fold over till the skirt has a regular shape, and then it is folded in gores, the fewer in number of course the better. If buttons are on skirts or bodices, white tissue paper should be put over every one to prevent their impressing the material and in all light clothing, white tissue paper will be found of immense value if placed between each fold. It protects the first, and keeps the garments in splendid condition. This should also be remembered in laying away gloves. Each glove should be wrapped in tissue paper after the fingers have been stretched, the thumb tucked in place and the inside of the glove aired after wearing. It is a pernicious habit to roll the gloves one inside the other immediately after removing from the hands, and the new look will soon be ruined in this way. Boots should be stuffed with paper instantly they are removed from the foot, unless trees are available, and the same pair of shoes should never be worn two days in suc-

cession. The habit of changing gown and foot gear when indoors is very economy.

Clothing, Hygienic. In a climate so changeable as ours, cotton underclothing should never take the place of woollen. During the summer, if flannel cannot be borne, some fine woven woollen fabric should be worn next the skin. When linen is employed it should be changed frequently. Better pay out money for the laundry than for the doctor. All clothes should fit comfortably, and especially should not be tight. Fashion need not be disregarded, but should always be made to bend to comfort and health.

Coffure, The. This French term implies more than the mere arrangement of the hair, the style of which should always be suited to the contour and complexion of the wearer's features, and so dressed as to enhance the wearer's beauty. The daily hygiene of the hair is a matter to which serious consideration must be given if good results are to be secured and maintained. It, of course, varies with the individual; hair which is lank, or moist, or greasy (conditions usually found in the hair of nervous subjects, or of those who have much anxiety, mental worry, or stress of brain work) needs a totally different treatment from that which is dry and full of the scaly dust. (See also under **Hair**.) The hair specialists are by no means agreed as to general governing lines of treatment. Some have taught that the hair should be regularly cut, either at the new moon (to encourage a longer growth), or at the wane of the moon if extra thickness without increased length be desired. A smile may be evoked at the seeming lunacy of this moon idea, but there is method in the madness. Others are emphatic in laying down that it does the hair no good to cut it, and many have outlived the cutting with undoubted success. Then, again, while most of the hair specialists advocate a vigorous brushing of the hair from root to tip (with a convex brush, the bristles of which will penetrate to the scalp) from ten to twenty minutes night and morning; others say that no brush should be used, but that after the application of a few drops of a good hair-nourishing preparation, a thorough combing, beginning at the free end, with a special comb slipped to the head and made with a handle, for hygienic reasons, also without teeth, for the same reason, should be given, and that following this a soft piece of *glace* silk should be used, folded over a fairly thick strand of hair at a time, and then drawn rapidly over it. This is good practice; but the great thing is to bestow constant care upon "woman's crowning glory," ensuring cleanliness by gentle and frequent lavation, and the use of a pure and reliable soap like Pears', followed by patent smoothing and drying. As to making artificial additions to scant and falling locks, that is a matter for taste and discretion—especially the latter. Let it be remembered that the desire of a woman to have a luxuriant, richly-coloured, lustrous head of hair proceeds not only from vanity, as those who rage against the "transformation" would have us believe, but also from the very praiseworthy desire to show the sign of health and vigour. Nothing "lets a woman down" like appearing with thin and poorly-dressed hair, forgotten by Nature, abandoned by art, and neglected by its wearer. One owes herein a duty to one's self and country. But the restoration period should be taken in time and managed tactfully. (See also **Baldness and Hair**.)

Cold Cream, Home-made. This will be found reliable, and preferable to the unknown admixtures which are sometimes advertised under pretentious appellations. One ounce of good white wax, half an ounce spermaceti. Dissolve very gradually by placing, immersed in two ounces of olive oil in a basin near the fire. Cool upon amalgamation. Stir in three drops otto of rose, or orange-flower water to perfume it, and put away in a close-lidded pot or jar for use. It is an admirable emollient, quite free from irritating properties.

Cold Winds. (See **Complexion**.)
Colours and Complexions. Blue is unsuited to the brunette, because its orange reflection intensifies a dark complexion, but a blue veil will diminish the effect of bright light on the hue of any skin, just as blue spectacles preserve the eyes from the sunshine.

Light green increases the ruddiness of a warm complexion, and gives a heated appearance; to the pale blonde it is permissible, imparting enhanced rosiest. Sky-blue and its allied hues become the very fair, bringing into proximity with the dominating tint of their hair and complexion the complementary colouring. Reds, yellows, and oranges may be worn by the dark-haired and dark-complexioned with impunity, as enriching shades of blackness. But violet is treacherous wear, reflecting and augmenting yellowness of complexion or hair, and making blue seem green. If a woman of sallow skin would look her worst, let her adopt violet millinery.

Combs, Care of. Combs can be cleansed by working a piece of cardboard between their teeth, and afterwards rubbing them well with flannel. As tortoise shell combs are always prone to break easily, many may find this hint a useful one. If the combs be really of tortoise shell, the traces of joining should be invisible. First slope the margins of the break by scraping off the broken pieces for the distance of about a quarter of an inch from the edge; then overlap these margins, and when thus arranged, clamp them between a strong letter-clip, and immerse the comb in boiling water for some time. As the horn softens, it unites; and when dry again, the place where the break had been should be unnoticeable.

Complexion, The. Cleanliness has more than all else to do with promoting and keeping a clear complexion. Frequent and regular lavation, with the avoidance of all injurious soaps is the prime essential. (See **Baths and Bathing**.) Sound and refreshing sleep has a very beneficial effect upon the complexion. The habit of falling asleep at a few moments' notice is one to be encouraged in the interests of health—a more important consideration even than colouring, though inextricably bound up with it. After unusual fatigue, the face of even a young woman has a drawn and tired look which ages it palpably. A quarter of an hour's sound sleep removes this and replaces it by the soft countenance of well-rested youth and pink, which is the characteristic of the finest blonde complexion, or the rose and olive of the brunette. (See **Rest**.)

Much can be done to improve a poor complexion by plenty of exercise and hygienic living, as here and elsewhere insisted upon. Beyond this, steaming has a surprisingly good effect upon some sallow, thick-looking skins. Hold the face for a while over water as hot as it can be borne without scalding, keeping the eyes closed and the steam in with a sort of tent formed with a bath towel. Renew the hot water occasionally. Then wash with Pears' Soap and douche the face with cold soft water. The hot water opens the pores of the skin, the soap cleanses it, and the cold closes the pores and stimulates the skin to healthy action. It also braces it against the sun, the east wind, or frost. Some people rub in a little eau de cologne to finish the process, but this is not necessary; indeed, it is best to trust to the emollient and detergent effect of the soap.

To remove the painful smarting which results from exposure to the sun, especially in sea air, the following preparation is of value: An ounce of Pears' Soap dissolved in three ounces of orange-flower water, mixed with one and a half ounces oforris root dissolved in four ounces of spirits of wine. Let the mixture stand for two, pour it off the sediment, and pour a little into lukewarm soft water to bathe the face, particularly after exposure to the sun and wind. "Tan" can be removed from the face by the application of a little peroxide of hydrogen, diluted with water. Have it mixed by a chemist, and on no account made too strong. For "freckles" some recommend the application of buttermilk, and it can do no harm.

A serviceable complexion wash for use after exposure may be thus prepared: Peel a large cucumber or two, cut in slices, place in a double boiler closely covered, and cook slowly—without water—until soft. Put the pieces in a fine linen bag, and squeeze until all juice has been extracted; add to the juice one-fourth rectified spirits of wine (or whisky will do) and one-third elder-flower water. Shake well, pour into small bottles, and seal. The lotion may be applied several times a day at first, and less frequently when the skin has become clearer. Shake well before using.

The *skin in winter* is liable to become dry, tough, and red. To guard against these evils, a little cold cream (*q.v.*) should be applied after washing, and carefully wiped off, after which some Pears' Violet Powder should be dusted over the face, left on for a few minutes, and brushed off with a pad of cotton wool. For the hands, which generally suffer even more from winter weather, an excellent plan is to rub a mixture of glycerine and rose-water into them when half-dry, and finish the drying process thoroughly afterwards. This will keep the hands soft and white in the blithest weather, if gloves be constantly worn out of doors and an old pair used for sleeping purposes.

Sitting too closely over the fire, especially when fresh from a walk in the cold, is most injurious to the complexion, making the skin harsh and dry and encouraging premature wrinkles. To retain one's youthful appearance, the skin must be kept firm and elastic, and anything which helps to induce an unnatural dryness destroys the elasticity.

Complexion in connection with diet. Diet has a great effect upon the complexion. Simple food, as varied as possible and cooked to perfection, is good for both health and looks. Simple dishes eaten with relish, and digested merrily, not sadly, bring brightness to the eyes and freshness to the cheeks. Most of us eat too much meat and not enough vegetables and fruit. Fresh water-cress is a specially good blood purifier. It should be eaten at breakfast and each meal during the day whenever obtainable, with plenty of salt. See also that it is thoroughly well washed. Not only does water-cress give a clear complexion, but it also produces a fresh, bright colour, as it has the peculiar faculty of absorbing iron from the water in which it grows.

Vells are harmful to the complexion, unless they are diaphanous, and of sufficiently open texture to admit the air whilst excluding grit; the skin needs the friction of the air. Constant covering interferes with the circulation and the healthy action of the pores. It heats the face, and keeps it covered with an oily moisture which catches the dust and dirt, despite the veil, and gets into the pores. When the face is left exposed to the air the dust is largely blown off, and the skin remains dry and clean. In *motoring* even within the legal speed limit—velts are a superfluity; and eye-protecting goggles—ugliness's supreme invention—are dispensable, except on a high head-wind. Have your air-bath for the face on a journey, and your water-wash on reaching the end, and the complexion will sustain no hurt.

But in all matters of the complexion remember the testimony and commendation of Adolpha Patti, "Pears' Soap is matchless for the complexion."

Corns. When these are contracted every effort should be made for their eradication, otherwise all the observances of the toilet generally will "leave something to be desired." Here is a good recipe, which should be compounded specially by your chemist according to direction. In one drachm of absolute alcohol dissolve and mix forty grains of salicylic acid and six grains of extract of Indian hellebore. When these are intimately blended, mix up to one ounce with flexible collodion, and again blend thoroughly. Before you apply this to your corns, soak your feet in hot water, in which you have dissolved a lump of common soda, dry, and give each corn one thorough application. Repeat the whole process every night until the corns disappear, but after the first night you should peel off the collodion coating before you cleanse the feet or while doing so. Thus may corns be banished, and they will not reappear if the feet be regularly exercised and good-fitting boots worn. Remember, however, that it is quite as bad to have boots too loose as too tight; in the first case corns are induced by friction, in the second by undue pressure. (See Feet.)

Corsets. Where corsets are worn—and almost every woman wears them where civilization reaches them well-fitting, so as to afford bodily support without stricture. It is tight lacing and hurtful pressure which render stays and corsets a menace; their abuse, not their use, calls for condemnation. The much

abused Dame Fashion sometimes does us a good turn, and her course in the matter of corsets for the past few years is distinctly such. The days of wasp waists (and they return periodically) are always sad ones for woman-kind; but the corset which compresses the superfluous flesh about the hips, and gives support to the lower portion of the body where most women are conscious of a sense of weakness, is robbed of all its injurious effects. A corset must not compress the vital organs, but with the straight-fronted modes, the lungs, heart, and stomach are left quite free. To obtain the best results as to beauty of figure, the corset should be laced with three separate laces. The upper one is threaded till about three holes above the waist line, the second includes only four or five eyelets just at the waist, and the third extends to the lowest eyelets of the corset. It is most important the stays are adjusted properly, and that means placed lower on the body than is usually done. The suspenders are then fastened and after all this is done, the stays are laced to a comfortable tightness. Before the lacing is accomplished, the hands should be placed inside of the corset, and the superfluous flesh drawn above the waist line. Thus prevents the lacing from compressing a vital part, and also improves the figure. If a figure has become too spread, as is so often the case in middle life, care of this sort will do much toward restoring it to attractive lines. It is a mistake to have a corset closely boned, and that is why a cheap corset is seldom a success. The bones need to be fitted in other directions besides from top to bottom, and it is only a skillful corseteer who can do this successfully. The example of the French women who buy a good corset, no matter how inferior the dress, can be followed with advantage. It is ruinous to a figure to sit around the house or work without stays. All sorts of bad habits as to carriage are formed, and on the other hand, if household duties are performed, special and loosely-laced stays should be worn. (See also Waist.)

Comestics. Soap and water come first in the category; purity is a *sine qua non* in the soap, softness in the water. Then a simple cold cream (for which a recipe is given, *ante*), will be found very serviceable. Always be careful to rinse away soap after washing. Eau de Cologne, fresh, yet diluted, is good. For powders keep to Pears', it is safe and effectual where needed. Rouge has been superseded by carmine, that should only be employed with caution and sparingly; bluish preparations are always hazardous. Glycerine induces growth of hair and is not good for the face. A cold cream with vegetable fat as basis is good, and pure olive oil is excellent though darkening to the skin. The powder puff should be a good one of swan's down, and kept boxed away from dust. For the rest, specific cosmetics for various contingencies are referred to in their proper order; but the less they are required and employed the better? Absolute cleanliness is far preferable to plastering the bloom of health to any enamel.

Costume is a very important toilet matter indeed. All apparel and dress accessories should be becoming as to coloration (see Coloration and Complexion), and also, in design and make-up, adapted to suit of the most advantageous presentation of the figure of the wearer; not over-obtrusive of specially good points, nor too obviously fashioned for the hiding of imperfections. Suitability ought to have precedence of smartness in all things, and good taste govern in regard to what to wear, and how and when to wear it. Conform to convention as far as you can, and avoid conspicuousness, whatever the cost; that way vulgarity lies. The best-dressed girls and women, from the standpoint of harmony and real effectiveness, are by no means those who spend the most money, relatively to their status, on fancied adornment. The "fitness of things" must never be lost sight of. Nor should mere cheapness of material be permitted to influence selection at all. The "correct style" in dressmaking is that in which the most is made of well-chosen fabrics, of the best procurable quality, in the interests of the wearer's personality and pocket; and the millinery, jewellery, and etceteras should match on all occasions, comfort as well as suitability being

constantly studied. Let each apply these maxims to her own individuality, whether she be short or tall, stout or thin, dark or fair, young or old; they constitute the "golden rule" as respects costume, and allow a wide range for womanly resource and gratification. (See **Two Figures, The.**)

"**Grown-ups.**" (See **Face** and **Wrinkles.**)

"**Curling the Hair.**" (See **Hair.**)

"**Dentifrices.**" Good simple dentifrices are camphorated chalk, brushed well over the teeth regularly, with clear water rinsing to follow; or powdered borax dissolved in tepid water, to which a little of tincture of myrrh may be added if desired. (See also **Breath-Sweeteners** and **Teeth.**)

"**Deplatories.**" (See **Electrolysis.**)

Diet has a deal to do with rendering trouble taken with the toilet successful or otherwise. If you want to have a good complexion eschew greasy foods, cakes, pastry, and sweets, as well as all highly seasoned dishes. Don't eat between meals. Eat plenty of fruit (fresh and stewed) and green vegetables, underdone beef and mutton, white fish and milk puddings. Abstain from strong tea and coffee, and if you find that any special food disagrees with you, give it up at once. The stomach quickly reacts on the skin, and takes its revenge by giving it a muddy look. The "rigour of the game" in "beauty cult" entails a very strict regimen as regards feeding. An authority on this theme enjoins that "the menu for a would-be beauty must be of the simplest. Two meals a day are the most of which she may partake, and at those the range of choice is decidedly limited. No breakfast is allowed, but a glass of cold water, an orange, or an apple may be taken if desired. The first meal of the day is a mixture of breakfast and lunch, and is eaten at noon. It consists of a good vegetable soup, some nuts (walnuts chopped fine, or chestnuts hulled and mashed or roasted), cheese, brown bread, and butter, chocolate, and for drink either warm milk or cold water. The second and only other meal is partaken of about 7 p.m., and differs very slightly from the first. A soup of lentils or haricots is followed by eggs, whole-meal bread, and various vegetables; salads are allowed, and any fruit which may be in season, with cream. For purposes of digestion, a glass of Vichy water may be taken half an hour afterwards. This "perfect health diet" is said to impart a skin of velvety softness and of faultless tone to those who will carefully follow it. All the vegetables, however, must be cooked by steam alone and served with a little olive oil, while no salted butter may be taken at any time. Plenty of pure cold water is recommended for drinking, as water is most beneficial for building up the wasting tissues. This is severely simple living, carried to the extreme of cautious system, and would entail too much self-deprivation for most folk; but it points the right way. Bacon and all salted meats must be abstained from altogether by those subject to rashes or eruptions, at any rate when symptoms of the skin trouble appear. (See also **Complexion.**)

Electrolysis is by many deemed the surest of depilatories; but for its practice expert professional skill is requisite. It gets to the root of the trouble, which no caustic application can accomplish without occasioning harm in excess of the good it does, and the plucking out of superfluous hairs rarely sees the end of the matter. Electrolysis is recommended as a valuable outside aid to the toilet of all requiring and able to obtain the benefits it can convey. Not only is it of depilatory effectuality, but it can be applied to the cure of nervous affections, to the removal of the trouble of scabs, outgrowths, or indentations occasioned by injury or disease. But no "quack" male or female, will be permitted to apply the electric needle to any part of any wise person.

Exercise should supplement the toilet; exercise of every rational sort, muscular and of the respiratory organs (see **Breathing Exercises**). The brisk walk is a very potential benefactor. If taken regularly in the purest available air, it will give great assistance to the healthy in the way of conserving their good condition; it will help to thin the fat (see **Obesity**), it will develop the abnormally thin. Then "Exercise, Exercise, Exercise"—every morning, and as early as

you can. Don't say you "haven't time"; make time, adjusting your rest and your daily duties accordingly. Your good looks and good spirits will be your long lasting reward. (See also **Massage.**)

Expression. No face can be beautiful, no matter how richly endowed with regular features, if the expression is not charming. It need not be weakly amiable, but must indicate intelligence, the power of observation, and general kindness. The matter of cultivating a good expression is worth every woman's notice. Very far-reaching are the words, "Know thyself," and of more than biblical significance. A woman should have a hand-mirror, and sit by herself in a thoughtful and serious mood to try to know herself—not with the hope that the mirror will return a flattering message, but in the full glare of daylight (face to the light) and search for imperfections. A line here will tell her that she compresses her mouth when sewing; a wrinkle there will testify that when she reads she frowns; and a horrid little thing, which she tries in vain to brush away, will suggest the necessity of massage around the eyes. I wonder if there was ever a woman who did not think that her first "crow's foot" was a hair! If you study the faces of fellow passengers in the omnibus, or in other commonplace public vehicles, you will be astonished to find how really few persons have a nice expression when the features are in repose. One wears a worried look; her neighbour a discontented one; another has an unreliable and weak expression about the mouth, which would perhaps prevent her successful application for an appointment. The prospective employer would say she had a weak mouth, for most people who pride themselves on being students of human nature are very superficial, and to them a drooping mouth means melancholy, a lifted corner a sneer, etc. In reality, there are many qualifications for each mark of expression, but in the instance named, the mouth may be perfectly well-shaped, and the unpleasant expression merely a matter of an unfortunate habit. Rounding corners of the mouth are not looked upon with favour, and usually indicate a real necessity for a change in character. The habit of observing will cultivate a nice expression of the eye, and the smile should be studied most of all. If the teeth are ugly, there is no reason why a smile should reveal them aggressively to the world. I hear someone say that this will induce affliction, but that does not at all follow. There is much that can be done on these lines, but a word to the wise—and what woman is not wise!—is sufficient!

Eyes. An eminent writer has remarked, "Most children are born with light eyes, but a great many of them exchange them for dark eyes as soon as they realise their mistake." The relative beauty of light or dark eyes is, however, as in every case of individual beauty, merely a matter of taste. Beauty must be "in the eye of the beholder" as well as in the eye that is looked upon. Time was when novelists made the dark-eyed girl "as dark of soul as were her orbs," while all the virtues were ascribed to the blue-eyed maidens. Thackeray tried to upset this theory by giving his dark-eyed heroines depth of soul and making the blue-eyed damsels treacherous. Be that as it may, the beauty of the eye is not so much a matter of colour as of shape, size, and expression, and the cleanness of the white surrounding the iris. Still, colour is an important factor in the attractiveness of the eye and has to be counted with. Brightness, softness, sympathy, are the leading qualities.

To keep the eyes clear and bright they should not be subjected to unnecessary strain. Nothing can be more injurious to the eyes than to strain the sight by reading or working in an uncertain light. Never read in a doubtful light, and always have the light falling upon the book from behind. Do not expose the eyes to the glare of strong sunlight unduly, or to that of brilliantly-illuminated places of assembly; and be careful to protect them from injury by dust and other foreign substances. "Washing your eyes" is good homely counsel. Some people suffer from a constant inflammation of the eyes, which not only causes them much discomfort, but seriously detracts from the beauty of the organs of vision. The most efficacious eye-wash in a case like this is a mixture of borax and

camphor-water—not spirits of camphor. The proportions should be ten grains of borax to an ounce of camphor water. Always, in making the toilet, carefully bathe the eyes. When the eyes are weak no better or more harmless lotion can be found with which to bathe them than diluted cold tea.

Eyebrows. The eyebrows can be trained to almost any shape by the exercise of patience and care. When the growth is thick and bushy, they can be trained with the tips of the fingers to grow in the desired shape. Dip the finger-tips into a little rose-oil before manipulating. When the line is uneven the offending hairs may be removed with a pair of small tweezers, or treated by electrolysis. If the eyebrows are too thin, clip them neatly and cautiously with sharp curved scissors and rub into them a little good cream or vasoline at night. This will in a short time appreciably improve the growth.

Eyelashes. The longer, thicker, yet silkier the lashes the greater beauty will they lend to the eyes. Clipping the eyelashes once in every two or three months is very beneficial to them. It should, however, be done with extreme care, a pair of curved scissors being used. The tinting or colouration of the eyelashes is all very well for stage effect; otherwise, it is best left alone. Nature provides lashes of the right hue, for all eyes; the owners have only to keep them in trim, not try to change their hue.

Face. The care and assiduity in cleansing the face cannot be too strongly insisted upon; neither can the necessity for using only the most reliable soap be over-emphasised; and here it need only be said that Pears' is "the purest and the best." Steaming the face occasionally is commendable. To do this without going to the expense of elaborate apparatus, place about a quart of boiling water into a hand-basin, hold the face, with the hair well pinned back and a handkerchief folded across the eyes, over the basin, and throw a large Turkish towel over the head, letting the ends fall round the basin to keep the steam in. This will open all the pores of the face, and the skin should be carefully wiped with a soft linen rag or pad of cotton wool afterwards. Gentle friction is good for the face; so is massage, which keeps the muscular tissues in tone. Puffiness under the eyes is often due to a relaxed condition of the skin. The best remedy will be found in the use of a lotion, composed of twenty grains of tannic acid to an ounce of glycerine. It should be applied night and morning with a fine camel's hair brush. See also **Bathing**, and **Complexion**.

Fat, to Reduce. (See **Obesity**.)

Feet. The. No one can possibly be healthy who does not keep the feet scrupulously clean. In the spring and summer, when the warm weather induces increased perspiration, it is not too often to wash the feet every night before retiring to rest. This should be done in cold water, excepting in cases when this is found to give the lather a chill, when tepid water should be substituted. An octogenarian once told the writer, in reply to a query as to how she had such marvellous health at her advanced age, that she had washed her feet regularly, without intermission, every night since she was a child, and to that fact, and to the wearing of soft, well-fitting boots she attributed her having passed through life without illness. There is nothing soutilless sore, tired feet so much as immersion in warm water, and they are strengthened if a little castal is added. Care should be bestowed on the regular trimming of the toe nails, after bathing the feet.

A good authority on boots asserts that a woman with large, unshapely feet can only afford to wear a laced boot, and never a low shoe of any kind. Button-boots are not to be recommended as a pretty foot suffers considerably in them. No matter how firm the buttons, they "give" to the motions of the feet, and, if worn regularly, entirely ruin a shapely ankle. Laced boots, on the other hand, tend greatly towards the correction of any faults a foot may possess. Button-boots encourage the spreading out and unnatural development of a good-shaped foot, and are the cause of many a weak ankle. Never run in the toes into pointed shoes, but leave them room for free and separate motion. (See also **Cornea**.)

Blistered Feet are always painful. Those subject to

them are advised to wear soft, good-fitting, marine socks or stockings, and at night to take a small portion of Russian tallow, drop it in cold water, rub it on the palm of the hand with a few drops of brandy, and apply to the blistered places. This will have a very healing effect.

Boots and Stockings should always fit quite comfortably; people often make the mistake of thinking that tight-fitting boots are the sole cause of corns. Boots and shoes that are too large are equally fruitful in producing them. All foot-gear should fit perfectly, not too tight, and not too roomy. Again it is a mistake that many women fall into, to wear thick woollen stockings in winter. This sort of hosiery renders the feet tender, and causes undue perspiration. Cashmere is infinitely to be preferred, and can be worn well on into the summer, until cotton, Lisle thread, or spun silk are adopted instead. Care should always be taken that the stockings do not wrinkle, as this also causes the skin to harden, and ultimately induces corns. The same thing occurs when heavy leather boots and shoes are worn, and it is well to be particular when selecting new footwear of any kind to get soft makes, and, if possible, the very best. This, in the end, is the truest economy; poor footwear is a terrible "let down" to anyone aspiring to dress well or look well.

Figure. The. One ought to make the best of one's figure. Not by tight-lacing to malforn the waist (see **Waist**); but by exercise and hygienic living to cultivate symmetry, grace, and correct deportment. Angularity is often as much a matter of habit as of actual physical structure; adiposity, the outgrowth of idleness, "scragginess," the penalty of neglect. The figure to be clothed should be clothed according to its attributes and contours; not concealed by an imitation of some other person's habiliments, that other person being, very likely, built on totally differing lines. The tall figure ought not, as a rule, to be dressed in white or very light raiment, or further elongated by towering headgear. Light-coloured, loose clothing will, however, tone down excessive height to the eye. The well-proportioned of good average height may wear any material of hues not out of harmony with their complexion, almost any patterns; but the full figure looks best in dark or subdued shades, while striping in the design for the buxom ought to be narrow, and meshed in the draping to give length of line up and down, not width-wise. The tall can appropriately have a horizontal trimming and pattern scheme; the dumpy should don the longest and plainest skirts they can carry, eschewing large patterns and criss-cross lines. Skirts, sleeves will not do for the "skinny" and angular, nor will low-cut bodices; but square bodices can be made to cover concavities of collar-bone with out advertising their utility in this respect. Waist gatherings may be adjusted to supply a seeming fullness to the frail by the clever cooper, while fold arrangements across the chest can be expertly managed to "suit all figures." When the feet and ankles are not handsome the skirts may be worn long enough to render the fact unobtrusive, and so on.

Flushing may be the outcome of nervousness, want of self-control, or hurrying from one entourage to another. Again, it may arise from indigestion. The fume powder-puff is powerless to conceal it altogether. But conformation to hygienic conditions will usually obviate it.

Food. (See **Diet**.)

Freckles. (See **Complexion**.)

Frost, Protection Against. (See **Complexion**.)

Gloves form an important item of toilet appanage, adding to, or detracting from, the good appearance of the hands, as well as forming the appropriate protection out of doors. They should always be carefully chosen, and there are more important considerations than their colour and the number of the buttons. Black gloves are generally less elastic than light or coloured ones, and cheap grades are dear at any price. Dressed kid usually retains its freshness longer than the more durable but less elastic and less serviceable kid is soft and yielding. A glove so small that it cramps the hand and prevents grace of motion gives poor service. Short fingered gloves are ugly

and certain to break soon between the fingers, if not at the tips. The way in which a glove is first drawn on and shaped to the hand has much to do with both its beauty and durability.

Grey Hair, Keeping in Condition, and Grey Hair, Preventing. (See **Hair**.)

Hair Dressing. (See **Coffure**.)

Hair, The. Rubbing the hair down with a clean silk handkerchief every day, after brushing, has a wonderfully brightening effect. But to keep the hair glossy and bright, it should be well brushed every night with long even strokes of the brush and a strengthening lotion frictioned into it occasionally. An ounce of cantharides mixed with six ounces of castor oil, scented with eau de Cologne and rubbed into the roots, is good both for the growth and appearance of the hair. One thing to be remembered about the hair is that it appreciates the air and sunshine as much as do the flowers. It is an excellent plan to occasionally let the hair hang down over the shoulders, and to sit in the sunshine with it like that. To wear the hair dressed all day and then at night retire with it closely plaited, is to do it a serious injury. In most cases the natural oil of the hair becomes insufficient for its needs in middle life, and it is well to rub into the scalp a little pure olive oil, or to brush the hair twice weekly with a brush dipped in brillantane. Washing the hair in soda will make it brittle, although it produces a "fluffiness" which many like, and helps the hair to dry easily. Borax has the same good effects without being injurious. The hair should be brushed thoroughly night and morning, not a few hasty whisks of the brush, but long, even strokes, with a firm bristled brush. Whalebone brushes are good, and brushing continued with one for the space of five minutes will work wonders. Metallic brushes should be avoided. The hair cannot grow at all if the ends are split, and therefore a monthly singeing is advisable. To accomplish this, the hair should be divided into strands, each about the size of the little finger, and twisted hard. Hold the lower end of the strand in the left hand, and pass the partly-closed right hand to the roots, thereby exposing all the unruly ends, with a lighted taper these can be easily singed. I do not advise the cutting of the hair, but if it is done, the ends should be cauterised; if not the hair literally "bleeds," and vitality escapes. There is a system of circulation in each tube of hair, quite similar to that of the human body, and there is no part of the body which responds more gratefully to any attention or care.

Regular Shampooing. once every three weeks or a month, is advisable for the hair. An excellent and inexpensive shampoo can be prepared at home in the following way:—Shave about a pound and a half of Pears' soap into a quart of hot water, add to it a large teaspoonful of powdered borax, and a pint of bay rum. Rub this well into the roots of the hair with gentle friction, rinse out all the soap with warm water, and after it is quite dry rub a very little rose oil into the roots. This treatment will give the hair a beautiful silky appearance.

Another good hair wash, which may be given with advantage occasionally, is made thus:—Pour one quart of boiling water upon a piece of rock ammonia as large as a ribbit, and when cool enough to put the hand in, work to a lather by heating. Rub well into the roots of the hair, then into the hair itself. Afterwards wash out the lather with cold water, and also douche with cold.

When the hair appears dry and lifeless after its regular washing, it is a sign that it needs a little tonic, and this can be given it by mixing two tablespoonfuls of castor oil and the same quantity of glycerine into a four-ounce bottle with enough alcohol to set the oil. Shake the mixture until it is thoroughly mixed, roots massage a few drops into the roots of the hair with the tips of the fingers.

To prevent light or golden hair going dark, beat up the yolks of two quite fresh eggs with half an ounce (one tablespoonful) of tincture of Quillaia saponaria, and with a toilet glove rub the whole of this mixture well into the scalp. Next in a quart of hot soft water beat up one ounce of the same tincture, and a heaped tablespoonful of powdered borax

(dissolve this first in two tablespoonfuls of tepid water) and then wash the hair in the liquid. This will produce a plentiful lather when rubbed into the egg mixture already on the head, and may be removed by copious rinsing, first in hot soft water and then in cooler. Dry with hot towels.

Hair may be kept from going grey prematurely sometimes. Take a wash of alcohol and strong black tea in equal parts. Add to this a handful of kitchen salt. This forms a simple and harmless remedy, and will often not only arrest the greyness but strengthen the hair and increase its growth.

Grey hair can be made to keep its silvery tone if constantly washed and rinsed in clear water in which a little blue has been shaken.

For falling hair an excellent preparation is made by adding to eight ounces of alcohol (spirits of wine), half an ounce each of glycerine, spirits of lavender, and tincture of cantharides. Eight grains of sulphate of quinine are then added, and the mixture well shaken. Any perfume desired may be used for scenting it, and it should be well rubbed into the hair night and morning. (See also **Baldness**.)

Another recommended hair preserver is made thus: Take half an ounce of camphor (finely powdered) and moisten with two tablespoonfuls of gin. Put this into a pint bottle and fill with water. Apply with a sponge to the roots of the hair twice every week. Brush the hair at least once daily, using a brush with rather long, soft bristles. This "preserver" will promote the growth of the hair, besides keeping it clean, soft, and glossy.

Curling fluid for the hair may be made and used thus: Take two ounces of borax, one dram of gum arabic, and mix with a quart of boiling water. Stir until fully dissolved and add three tablespoonfuls of spirits of camphor. Damp the hair with this before using the waving irons and the crimp will remain in it during the most inclement weather.

Another curling method. To obtain a permanent artificial wave in the hair, rub a little scented vaseline upon it, leaving it on for a few minutes and then wiping it off with a soft linen rag. After this apply the waving irons, and the hair will retain its wave for a long time in spite of wind and damp. A great deal of the successful waving of the hair depends upon heating the irons employed to the correct temperature. If they are too hot they will dry the hair and render it harsh and brittle, while when too cold they will make but a trifling effect upon it.

Hands. The care of the hands is an important toilet consideration. An excellent and simple wash for keeping the hands white and smooth is made of equal parts of vinegar and water. It is a good plan to keep a bottle of it prepared and standing in the kitchen closet. Wash the hands first thoroughly in warm water, wipe them dry, and rinse well in the mixture. The same preparation is good for removing stains from the hands.

Use gloves at housework whenever practicable. In dusting, for instance, wear a pair of the chamois leather gloves sold at the stores under the name of housemaid's gloves. They cost little and last a long time, and keep the hands and nails quite nice.

To whiten the hands this is a good recipe: Twenty drops of tincture of benzoin, dissolved in one ounce of eau de Cologne. Add ten ounces of elderflower water and the strained juice of two lemons (or of a lemon if you cannot get lemons). Shake well each day for a week or two in a bottle and apply at night, after washing, with a soft piece of flannel or sponge, letting it dry in.

As a preventive of chapped hands nothing is better than an application of rosewater and glycerine well rubbed in after washing, before the hands are perfectly dry, the drying process being finished afterwards. When already badly chapped, a few drops of pure glycerine should be placed in the palm of one hand and well rubbed into the other, and a pair of loose-fitting gloves worn during the night. The application of pure glycerine to hands which are badly chapped is rather a heroic remedy, but it is more efficacious than anything else, all trace of roughness disappearing in the course of one or two applications.

A good plan is to keep a camphor-ice ball on the washstand and rub it over your hands before drying them. Be careful not to go out without care.

Hair, Choosing. Considerations of height, shape of face, complexion, and the age of the wearer, enter into the wise selection of headgear. Heavy trimmings and angular or eccentric shapes are difficult to "carry off" gracefully; and bonnets and toques, however modelled and ornamented, should frame the head completely, the hair arrangement being managed to accord with and complete the general effect. A large hat may be draped and trimmed to "set" and look light; and as to the colours employed in millinery, the aim ought to be to harmonise with and "bring out" dominant tints of eyes, hair, and complexion, and so brighten the entire presentment. The right shades in white or the lighter colours are usually becoming; intense hues and deep black, unless properly relieved by the trimming, the reverse. Green or white ought to be interposed between the skin and a hat with pink body colour; and assertive ornamentation should be avoided; the object of headgear being, with the discriminating, to provide an appropriate and artistic framing for, and not to detract attention from, the face.

Hollow Cheeks. (See Cheeks.)
Hygienic Clothing. (See Clothing, Costume, Corsets, Feet, Waist, &c.)
Indigestion has much to do with the promotion of the skin ailments which occasion so much trouble at the toilet, and are often difficult of treatment if unchecked. (See Diet.)

Lips, The. The skin of the lips is the most delicate of the whole body, and once the lips are allowed to get into a cracked and blackened condition, it is most difficult to induce them to become soft and smooth again. They can, however, be kept so that this painful and unsightly condition does not arise. Many women have a pernicious habit of biting the lips, which, besides spoiling the shape, renders the skin thick and coarse, and is one of the chief causes of chaps and cracks. Whenever the toilet is made, and before going out into the open air, the lips should be lightly rubbed with a little pure glycerine. This is to be preferred to the coloured pigments sold as "lip-salve," for the latter give a painted and unnatural colour, which is by no means becoming.

Looking Glasses should be good, well placed as to light, and, if swung, adjusted at the right angle. The thicker the glass the better, provided it be clear and flawless. It should afford a pure white reflection of pure white paper at any reasonable distance, and give no distortion of form or variation in shade in the pictures it presents of the objects placed before it. Let it be kept quite clear by frequent polishings with soft material; should this be regularly attended to no other cleaning will be requisite.

Manicuring. (See Nails.)
Massage. Massage, properly carried out, is good for giving tone to relaxed muscles, restoring plumpness, and banishing wrinkles, wherever they appear. It also acts as a preventive against this undesirable condition, and is particularly valuable when skillfully applied to the delicate muscles of the face. The woman who is going to give her own face a "course," must remember that the skin of her face cannot stand very rough handling, and that the lines and wrinkles which she desires to banish must be gently smoothed and patted out. To obtain the best result, the finger tips should be dipped in salt and water before starting the manipulation, and constantly during the process, as the salt helps to stimulate the tired muscles. If preferred, however, warm olive oil may be substituted for the salt and water, or oil of sweet almonds may be used to moisten the finger-tips. In the latter case, the face should be slightly heated by the application of warm cloths before the massage is commenced. (See also Arms; Cheeks, Hollow; Chin, Double; Neck; Wrinkles; and Youthful Looks, To Preserve.)

Mouth Washes. (See Breath Sweeteners.)
Nails, The. Once a week the nails should be pared and neatly rounded, both on fingers and toes, for comfort and convenience. It is not at all necessary to employ a professional manicurist to obtain satis-

factory results with the nails, however well off one may be. Soak hands or feet for fully ten minutes in warm, soapy water, in which are a few drops of lemon juice, before commencing operations. This will soften and loosen the cuticle. Paring done, and filing down, attended to where necessary at the edges, apply an orange-stick—procureable at any pharmacy—to each nail, raising and pushing the skin from the nail. Dip the point of the stick in a little piece of lemon and clean the nails, after which rub them with a little vaseline. Wipe the vaseline off with a soft rag and polish with powder and the nail polisher. Because the toe-nails are usually out of sight, they are often neglected, but not by the wise. They require as much care as the nails of the fingers. Manicure "sets" can be obtained at all prices, and no woman should be without these toilet accessories.

Neck, The. A graceful and well-proportioned neck is a very decided accompaniment of a beautiful face and figure, and the care of it is worthy of consideration, especially by women who go much into society. Whether the neck be too fat or too thin massage is equally beneficial. If it be too fat, judicious massage will do much to reduce the superfluous flesh, while if, on the other hand, it be too thin generous friction, with a small quantity of cod-liver oil or a mixture of vaseline and almond oil, in a very short space of time, change a thin and angular neck into one quite passable as regards beauty. The great fear in connection with the use of oils on the skin—the growth of superfluous hair—need not enter into the consideration of the treatment of the neck, as it is very seldom that there are any hair follicles on the neck which could be stimulated into growth by fatty substances.

Neck-tie Oil.—Just mentioned—is one of the most flesh-forming oils that can be obtained, and if once one can make up one's mind to bear with the unpleasant odour, it would be well worth a trial to those who are anxious to develop the neck nicely.

When the Neck is thin or "scraggy," it generally happens that the rest of the body is also of poor physique, and in this case care should be taken to improve the general health by liberal diet, flesh-forming foods, such as cod-liver oil, vegetable, and fruit. One of the best and surest ways of improving the appearance of the neck is by means of breathing exercises. The benefit of the continual practice of good breathing exercises upon the neck can easily be proved by careful notice of those who make singing a profession. They invariably have beautiful necks without any unsightly hollows. (See Breathing Exercises, Chin and Throat.)

Obesity should be guarded against by exercise and careful dietary, especially when middle age is approaching. Then it is that the tendency to put on too much flesh gives trouble to many, coincidentally with an inclination towards indolence. This must be combated. Shake off drowsy feeling; by resolute activity, do not give way to unnecessary indulgence in sleep. Walk and work, and regulate the dietary with care. It is not necessary to starve at all. If when you feel you are growing too stout you avoid fatty foods, substitute toast for bread, and take potatoes only in small quantities, you will probably bring your weight down. Drink hot water with your meals, also half a pint of it before going to bed, and take plenty of exercise of some agreeable kind. Meats may be eaten freely, but puddings and cakes sparingly.

Old Age. (See Age.)
Perfumes. Besides the scents sold ready prepared for use, many may be made up at home, suitable for every toilet purpose. Procure fresh flowers of any agreeable fragrance, and thin layers of cotton, which dip into the finest Florence or Lucie oil; sprinkle a small quantity of fine salt on the flowers, and lay them alternately, a layer of cotton and a layer of flowers, until an earthen vessel or wide-mouthed glass bottle is full. Tie the mouth close with a bladder, then place the bottle in a southern aspect to the heat of the sun, and in fifteen days, when uncovered, a fragrant oil may be expressed from the mass, equal to the essences ordinarily purchased at perfumery shops.
Eau de Cologne can be prepared by any person at home, in quantity, thus cheaply. Take one quart

of rectified spirits of wine (85 per cent. alcohol), five ounces of essence of lemon, twelve and a half drachms of essence of cedar, four ounces of essence of bergamot, one ounce of essence of lavender, and one ounce of tincture of benzoin. The essences should remain in the spirit for dissolution and amalgamation for a full week before distillation and bottling for use.

A good perfume, which is also a preventive against moths, may be made of the following ingredients: Take of cloves, caraway seeds, nutmeg, mace, cinnamon, and Tonquin beans, each one ounce; then add as much Florentine orris-root as will equal the other ingredients put together. Grind the whole well to powder and put it into little bags among your clothes, etc.

A dainty perfume for the breath is made of the white of an egg, the juice of a lemon, two teaspoonfuls of sugar, a dash of almond oil, and another of rose-water. These must be beaten and stirred for hours and then carefully bottled. A half-dozen drops in a wineglass of water and used to rinse the mouth will make the breath softly sweet.

Powder. (See **Complexion**, **Cosmetics**, **Teeth**, etc.)

Puffiness. (See **Face**.)

Red Hands. (See **Hands**.)

Red Skin. (See **Complexion**.)

Rest is as requisite as ablution and exercise, at the proper time, to enable one to obtain the best effect from the toilet, other things being equal. Never keep on, either with work or pleasure, until you are "done up." Get all the beauty sleep you can, remembering the sage old maxim that one hour before midnight is worth two afterwards. Eight hours' sleep is absolutely essential to the woman who wishes to keep the bloom of youth, and, whenever possible, she should close her eyes and rest completely for at least ten minutes during the day. Thus little rest, although it be numbered only by minutes, is more helpful than many would believe, but it must be an absolute rest. Try to let the mind remain a blank, and throw the whole weight of the body upon the couch, giving every muscle a complete relaxation. Another golden rule is, Don't worry. Look always on the bright side of things and cultivate cheerfulness, as worry is fatal to youth and beauty. (See also **Sleep** and **Tired Feeling**.)

Rough Skin. (See **Complexion**.)

Salts, Smelling. Lavender smelling-salts, which are so refreshing, are easily made at home, and here is a good way of doing it. Carbonate of ammonia, cut in squares, eight ounces; oil of lavender, half an ounce; oil of bergamot, half-ounce; oil of cloves, one fluid ounce; oil of cassia, half fluid ounce. Mix and rub the oils well together. Put the squares of ammonia into your smelling bottle. Pour enough of the mixture over the salts to cover them scantily.

Soap. (See **Hair**.)

Scent and Scent Sachets. (See **Perfumes**.)

Shampooing. (See **Hair**.)

Shaving is one of the chief toilet operations of the "mere male," and it may be made easy or irritating. First, the shaving requires a good and well-proven razor, kept sharp by "setting" when requisite, and skilful stropping at and during each time of using. Then the face should be steamed, if possible, or the beard softened by the application of hot water and the thorough subsequent rubbing in of good lather. If a stick of Pears' Shaving Soap be employed, there will be no trouble with the stiffest beard or the most sensitive skin. The thing to do is to rub in plenty of thick lather, then the razor will reap the "stubble" with the soap smoothly and painlessly, and if there be any gashing it will be the fault of the razor or the shaver. The "Shaving Sticks" sent out by Pears in such quantity are so expertly prepared that they permit of easy shaving with even cold water where hot is difficult to obtain—occasionally a great advantage—and they last a very long time.

Shoes. (See **Feet**.)

Shoulders may be kept shapely by exercise, and smooth and white by cleanliness and the conservation of the general health. Physical drill, skipping, and any pastime which calls into activity the muscles of

the arms and shoulders, should have every encouragement. Regular exercise of the right kind, to afford relaxation from the attitudes of compulsory restraint: occasioned by the daily avocation, must on no account be neglected. Round or drooping shoulders are the sure penalty of neglect. Those engaged in sedentary pursuits or condemned to do much stooping of any kind, ought to lean backwards whenever they can, not lounge further forward for momentary relief. Shoulder braces may be worn for support, where necessary, with advantage, elastic and broad of strap; and swinging from a suspended bar, held by the hands, is good; while swimming will afford especially beneficial exercise to the shoulders. If the muscles are given their due share of motion, tension, and retraction regularly, the beautiful natural slope—neither too pronounced nor too "squat"—of the shoulders will be preserved, with the proper plumpness and the pearly glow which no enamelling can successfully imitate.

Skin. (See **Complexion**, **Face**, **Indigestion**, **Sleep**, and **Wrinkles**.)

Sleep. Unless sound sleep in sufficiency be regularly obtained no amount of trouble taken with the toilet will have its adequate reward. Insomnia is a fell destroyer of beauty. Here is a recipe for its avoidance:—On retiring for the night place the feet on a really hot water-bottle, then take in sips a breakfast-cupful of hot milk, chocolate, or beef extract—one kind of nourishment one night, another the next. After that, have a handkerchief folded in four, saturated with equal parts of rectified spirit and cold water, laid across your forehead in such a way as to cover both temples. When the lights are out sleep should come to those who adopt this method.

Smelling Salts. (See **Salts**.)

Soap. Soaps for toilet purposes cannot be too carefully selected, for much of the success of nearly all the operations of the toilet depends upon the quality of the soap used. Soap is the leading agent in laying that foundation of perfect cleanliness without which the various functions of the toilet cannot be performed with necessary completeness. Inferior toilet soaps, whose defects are often disguised in strong perfumes or dubious colourings, should never be used for even the most ordinary acts of personal ablution, much less for the delicate offices pertaining to the making of the toilet and the preservation of physical beauty. It is not enough that a soap should make a profuse lather, or that it should easily remove dirt from the skin, for many pernicious soaps will under this surface service; what is wanted is a soap that has been specially prepared for the toilet by expert scientific knowledge, that contains only those ingredients which are kind, softening, soothing, and refreshing to the skin—a soap that carries with it the elements of both health and beauty—a soap that is natural and wholesome in all its components, and helps nature in obtaining one of the greatest of all attractions, a lovely complexion. Such a soap is Pears' Soap. For upwards of a hundred years this renowned soap has received the praise and commendation of leading scientists and the most celebrated beauties; and such an economy of production has been attained in its manufacture that it is obtainable at a price that brings it within the reach of all. Pears' Soap represents the highest standard of toilet soap that the art of man can make from nature's choicest materials; and is at once the safest and most reliable soap that can be brought in contact with the skin. It gives forth its delicate saponaceous qualities readily and adequately, and is at the same time the least wasteful of all toilet soaps.

Sponge. It is important to keep the bath and other sponges sweet and clean. An old way was to immerse them for several hours in cold buttermilk, washing out in clear water subsequently; but a better method is to soak in clean fresh water into which the juice of a lemon has been squeezed, any toilet sponge that may seem at all sticky. In buying sponges bear in mind that the best are the cheapest.

Steaming. Many people are undecided as to the advisability of steaming the face, but the treatment is an excellent one if properly carried out. On the other hand, much injury will be done if carelessly or ignorantly proceeded with. The proper way is to fill a tall

jug with boiling water, hold the face over it, and throw a towel over the head, covering also the jug, to prevent the escape of steam. The steam must not mix with the air before coming in contact with the face. Once or twice during the ten minutes of steaming wipe the face with a soft cloth. When the steaming is over, dash cold water on the face and wipe dry. Then apply some very good cold cream in a rotary movement from the tips of the fingers and again wipe. Never fail at this point of the process to apply an astringent lotion or Eau-de-Cologne, to contract the pores which have been relaxed by the steaming. Neglect of this will produce enlarged pores, than which there is nothing uglier or harder to get rid of. Now, dust the face all over with a healing powder, or better still, powdered oatmeal, and do not go out into the cold air for at least an hour. This treatment of the face once a week will accomplish a great deal in keeping the skin soft and youthful, but if steamed too long or too often, the skin will soon become "straggly."

Sunburn. (See Complexion.)

Style of Dress. It is obvious that a woman's beauty may be enhanced or very much marred by her style of dress. No one can lay down hard and fast rules, as each individual must be a law unto herself. A few general principles may be regarded as infallible guides. A woman looks taller in stripes and according to the same principle, the stout woman should avoid plaids. Curiously enough, the extremely large check does not so much increase the apparent size of the figure as do the small ones. Purple is a colour to be avoided by the prematurely old, or stout woman, but navy blue is a wise choice. The pointed finish to a bodice is only for the slender sisterhood. It is a common error to believe that the stout woman should wear the pointed basque, but this brings her waist-line some inches below where nature intended it, and furthermore increases its size. Bodices for the stout should end at the waist, and a narrow belt of lustreless material should be her choice. If the gown can be cut all in one, so much the better, but even the princess styles wrongly handled will spoil a naturally pretty figure. All light colours give size, but this does not apply to white. Thin materials over linings, or shaggy finishes are not so becoming to stout figures as are the smooth faced cloths, and satin, except the most supple waves, make one look matronly. Large hats should be worn by tall women, and a hat turned sharply up at the side seems to add inches to the short woman. A bow at the back of the neck, either of ribbon or tulle, has a curious effect of adding both height and dignity to the wearer, as does also a hat turned up at the back and having its brim to extend over the face. Horizontal trimmings are for the slender, and vertical bands for the stout.

Teeth. The first step towards possessing beautiful teeth is to have the proper brush for cleaning them. The brushes should be short and closely set, but not too stiff. In cleaning the teeth, there need be no alarm if the gums bleed. This is often Nature's way of relieving herself. Twice a day is the minimum of times that the teeth should be brushed, and after each time of eating, between the teeth after eating, and a little gentle massaging of the gums once a day, will help to prevent the disaster of "receding" gums. In most cases the mouth is inclined to be crowded with teeth, and many doctors advise having one or two drawn when the child is about ten years of age. The gums are then soft, and the teeth spread to fill the

spaces thus left. If when the teeth first make their appearance they are irregularly set, much can be done by manipulation, practised several times a day during babyhood, while the gums are yet plastic. In having the decayed tooth filled, always consult a reliable dentist as to the material of the tooth. In many cases it is not at all advisable to have the tooth stopped with gold, which pulls away from a too soft tooth and induces more decay, while a silver or composition filling is far more satisfactory. Sound teeth depend largely upon the general health and constitution, but many people permanently ruin what should have been a good set by misusing their teeth.

The tooth brush should never be too hard, as a very stiff brush is likely to irritate the gums and injure the enamel. When the teeth feel loose, as is sometimes the case, especially if a bad chill has been taken, the gums should be painted with sal volatile, a fine camel's-hair brush being used. Great care should be taken that the sal volatile does not come into contact with the lips, or blistering will be the result.

Spongy gums have a very pernicious effect upon the teeth. Where the first signs of "sponginess," or a tendency towards receding is noticed, an astringent lotion should be applied to them night and morning, until an improvement has permanently taken place. A very good astringent lotion is composed of tannin, bark, and myrrh. Any good chemist would mix these ingredients in their correct proportions if told for what purpose the lotion was required.

Each tooth should be cleaned by itself, front, back, and sides. Too often the fronts are well cared for, but the back and sides are badly neglected. While cleaning the teeth, the brush should not be moved from side to side, but up and down, from the gums to the edges of the teeth, taking care that the bristles of the brush pass between each tooth. These trifling precautions towards warding off decay will do wonders in preserving the teeth far on in one's life.

Tartar on the teeth is a trouble which is sometimes caused by indifferent cleansing, sometimes by the over frequent consumption of rich foods or sweets. In either case it is decidedly unpleasant, and can easily be removed from the teeth by a little magnesia. Place a little on the brush, and rub the tooth, or that portion of the teeth upon which the tartar appears, with it. After two or three applications, it will all disappear.

Discoloured teeth, from whatever cause, should have a little fine powdered pumice-stone used to them. This should be moistened, and applied to the tooth with an orange-wood, and well rubbed on the discoloured spots. It should afterwards be brushed off, and the mouth rinsed with an antiseptic wash. Pumice-stone powder is one of the best agents for keeping the teeth in good condition as regards colour, and if not used too often could not possibly do any harm to them.

Tooth powders and tooth waxes are many, and it is to a great extent a matter of personal fancy what sort is selected. Care, however, should be taken to discover if the one employed contains anything which would be injurious to the teeth. Powders which whiten the teeth generally do so at the expense of the enamel, of which they are covered, and in this way commence to sow the seeds of their future decay. Prepared chalk, although a great favourite with many people, has a tendency to make the teeth brittle and should therefore be used with caution.

A good tooth powder recipe is the following:—Mix well together two ounces each of sweet powder, orris root, and camphorated chalk. Add twelve drops of eucalyptus oil, and again mix. Keep in an airtight tin if possible.

Decaying Teeth should be taken in time, and a good dentist consulted immediately; for often by expert attention a tooth can be permanently saved, while if neglected it may get beyond repair, and although art can do much now in the matter of artificial teeth, such teeth can never equal one's own. Gold-filling at the right moment has preserved many a tooth for years in good working order, and saved much pain, inconvenience, and expense.

Thinness may be overcome in many cases by improving the general health and by the adoption of a

nutritious and generous dietary. Exercise should not be excessive, and over-fatigue particularly avoided; at the same time as much fresh air as possible is important, especially if there be incipient anæmia. Special care should be bestowed upon the toilet, and attention given to the suitability of the costume; the clothing being warm, yet light, and adapted to give freedom and encourage development. See also *Figure*.

Throat, The. To keep the throat slender and firm similar exercises to those recommended for the chin and neck (*q.v.*) can be indulged in with advantage.

"Tired Feeling." When a tired feeling arises, after some unusual exertion, a little rest should be taken if at all possible. All the garments should be loosened and a quarter of an hour spent in absolute rest, with every muscle at ease. After this a warm bath can be taken, with half a pint of toilet vinegar or eau de Cologne thrown into the water. After the bath a thorough friction with a little cold cream and a good soft towel, followed by a dash of orris-root powder dabbed on the skin. After dressing again, a delicious sense of freshness will be experienced. See also *Rest*, and *Sleep*.

Toilet Accessories. (See *Accessories*.)

Tonics. (See under *Complexion*, *Hair*, etc.)

Tooth Powders. (See *Teeth*.)

Vails. (See *Complexion*.)

Waist, The. Should the waist be too expansive to contribute to perfection of figure, systematic exercise may do something to mend matters. Such exercise may beneficially be taken in the bath-gown immediately before the morning bath, and with the window of the room in which they are done thrown wide open. Stand with heels together, and arms, with dumb-bells of suitable weight, extended down easily at the sides. With the weight of the body on the right leg, carry the left leg backwards, and at the same time extend the arms upwards as far as they will go, letting the eyes follow the direction of the bells. From this position, twist the trunk from the hips half round to the right, and then swing the bells down as far as they will go in front of the twisted body, and up to position above the head again. Resume the first position and repeat the whole of the exercise, but this time twist to the left. Work at this for ten minutes, taking a deep nasal inspiration between each repeat.

Many foolish girls, and women of maturer years also, in the endeavour to cultivate a sylph-like waist, resort to tight-lacing, and constrict themselves in corsets several sizes too small, suffering much pain and discomfort at the shrine of vanity. Some even go to the extent of sleeping in what used to be called "stays," which ought never to go beyond fulfilling the function the old name implies. Corsets should, wherever worn, be cut on anatomical principles, supporting and keeping the waist in proper and shapely compass, and affording absolute freedom to the vital organs. (See *Corsets*, and *Figure*.)

Winds, Protection against. (See *Complexion*.)

Wrinkles, to Avoid. Some wrinkles can be effaced and others prevented by less aggressive. In conjunction with daily treatment, be sure that you have not the habit of lifting the eyebrows, or contracting them, or that you do not laugh at every silly thing or weep as readily! Always remember that though tears may beautify the heart, they certainly do no good to the complexion. The salt water of tears or of perspiration should be wiped most carefully from the face. At night it is well to wash the face in warm water, in which there is a good lather of soap. Rinse in several waters, and in the last rinse, water put a few drops of lavender water. With the tips of the fingers, start in the middle of the forehead and pass outward to the temples as a first step for a ten minutes' massage. Repeat this movement several times and then work in a rotary movement at the corners of the

eyes. If there is a bad wrinkle at the side of the nose, hold the flesh firmly at one side of the line by pressing the fingers of one hand against it, and with the tips of the fingers on the other hand press gently up and down the line, principally up, and perform little circles of massage from the lips, outward across the face toward the ears. For treatment of wrinkles the direction of massage is always around and outward. Never stretch the muscles downward, and the tissues of the face should always be moved lightly, or they will be stretched, and the skin though improved at first, will eventually have a relaxed appearance, which is almost impossible to get rid of. A little good powder should be dusted in after a day-time massage, which must always be done with skin-food of some sort. Powder is a protection to the skin, but should be washed out thoroughly at night. In the morning no hot water or soap should be used, only the cold water in which are a few drops of toilet vinegar. (See *Face*, *Massage*, and *Youthful Looks, to Preserve*.)

Youthful Looks, to Preserve.—The first step towards looking young is to feel young, for as one feels young, one is generally bright and well, and looks it. To keep young-looking the wrinkles must not be permitted to appear upon the face, the chin must remain oval, no superfluous flesh being allowed to accumulate there, the step should still be light and elastic, the eye bright, the cheeks round and rosy, the throat slender and wrinkleless, for on a woman's throat are generally written the first signs of approaching age. The well-preserved woman must bestow great patience and care upon the complexion and the figure. The care of the complexion, so far as retaining a youthful appearance is concerned, consists—as has been indicated in preceding paragraphs—chiefly in eradicating, or, better still, preventing the appearance of, wrinkles and lines. As a general rule, it is the woman with a thin face and delicate physique who wrinkles early in life, while her plumper sister, though possibly escaping the wrinkles, has to reckon with the other evil—the loss of her youthful figure.

Massage, manual and mechanical, will do much, though rarely all, that is necessary in keeping wrinkles at bay. For some skins a good tonic lotion is of almost greater importance. One application of this character has been specified. The lotion should be applied every night after the face has been massaged with cold cream, and left to dry on the skin.

A light, springy step goes a long way towards preserving a youthful appearance, and this can be maintained to quite old age by those of ordinarily strong constitution, by taking a short brisk walk every day in the open air, and, whenever possible, in the sunshine. It is a very true saying that more people permit themselves to "rust out" than are actually worn out with the work of the years. We should endeavour to keep up our activity by resolution and will-power by every legitimate means.

The lines of the face, says a careful observer, inform one largely of a person's history. Horizontal lines across the forehead are found even in children who are rickety or idiots, and being out in the sun with the eyes unshaded will produce them permanently, but they are natural at forty or earlier. Vertical lines between the eyes denote thought and study, since deep concentration contracts the eyebrows; grief and worry produce the same effect, and, frequently repeated, leaves a permanent fold in the skin. Arched wrinkles just above the nose indicate extreme suffering, either mental or physical. The earliest wrinkles of all and the most unavoidable are those which run from either side of the nostril down to the mouth, and these are produced by smiling and even the motion of the jaws in masticating. But all these facial lines can be more or less ameliorated by the cultivation, systematically, of equability, and by taking timely pains with the massage treatments previously referred to. The preservation of youthful looks "pays" for any trouble it entails, providing always it be intelligently pursued.

PEARS'
of
DICTIONARY
THE NURSERY.

By Mrs. ADA S. BALLIN.
Editress of "Baby: the Mother's Magazine."

The First Year of a Baby's Life

By MRS. ADA S. BALLIN.

The first year of a baby's life is fraught with far more dangers than any other. All the battles of all the nations have not been responsible for so many deaths as carelessness and ignorance cause. In many parts of England at the present day, as many as one-fourth of all the infants born die within the first year of life, and generally from two causes: (1) exposure to cold, which is the cause of all the diseases of the respiratory organs, bronchitis. one of the chief causes of infantile mortality — and greatly retards growth, (2) improper feeding, from which result most of the diseases of the digestive organs, such as infantile diarrhoea, catarrh of the stomach, and other diseases, which carry off their thousands annually. Both causes, namely, exposure to cold and improper feeding, unite to swell the huge mortality which arises from what is called malnutrition, for if a child is not sufficiently warmly dressed, food which should go to nourish the body has to be expended in making heat, and the whole constitution suffers accordingly.

"A new-born child," says Dr. Braidwood, "may be regarded as a mass of animated clay, composed of different tissues, which, by proper exercise, may be developed into a healthy being, or be destroyed gradually or suddenly, by very simple means. All the tissues are at this stage of existence so delicate, and possess the power of such rapid growth, that, with care, they may be cultured to almost any extent, or may be stunted or otherwise altered, so as to lose their vitality at once, or remain amongst others of a healthy growth in an isolated condition. The healthy child develops into the healthy man, but a sickly infant can never become a truly healthy adult."

These are weighty words. They contain the essence of all the science which creates a healthy adult life, and which secures the happiness of an existence that must be a healthy one before any good gifts of life can be gained or enjoyed. What applies to the children of the rich, applies with equal force to the children of the poor. There is not one law for the healthy upbringing of the child of the well-to-do, and another law for the rearing of infants among the masses. Proper food, due attention to cleanliness, and especially to the care of the skin, pure air, clothing of a hygienic kind—such are the landmarks which guide the sensible mother or nurse in baby management.

A baby's basket should be of wicker, and be lined to match the cradle, with washing cretonne or print. It should be in readiness for use.

Baby's Basket. and stocked with the necessary articles well before the time of baby's expected advent. Among the essentials are a complete suit of clothes, a flannel apron, and a number of soft diapers. The requisite fittings should comprise:—

One packet of cord dressings and powder.
One packet of absorbent cotton wool.
Linen thread.
Needles, thimble, scissors, and cotton.
Sponge and square of flannel.
Cake of Pears' Soap.

Powder box.
Pot of grease, composed of equal parts of vaseline and zinc ointment.
Safety pins, large and small.
Thermometer for taking the temperature of room, food, or bath.

A flabby tongue shows debility, and that the digestion is impaired. In a new-born infant, the tongue is generally rather white, and this continues until the saliva becomes more plentiful. When the stomach and bowels are disturbed, and after other disease where the temperature is high, the tongue is coated, but this coating is not so important in young infants as in older children, because it is sometimes

due to the milk not being properly cleaned off the tongue after a meal. After every meal a corner of a silk handkerchief, dipped in water in which a little borax has been dissolved, should be well swabbed round the gums and mouth, and if this is done, that common disease of infancy, thrush, will never appear.

If a child is healthy, it enjoys its food at regular intervals, and food should be given at fixed and definite times. If the child is feverish the

Nursing. appetite is lost, and it is then undesirable to force it into feeding, but plenty of water should be given to drink. During the first six weeks of life a child should have three or four motions, like thick mustard in colour and consistency, during the day. If the motions are white, it shows that the liver is sluggish; if green and sour-smelling, that the child is acid. If curds are passed in the motions, the milk is not being properly digested.

Towards the end of the first year the motions become imperfectly formed, brownish in colour, and thicker. Their consistency gets greater as more solid food is taken. It is of the utmost importance that the mother should always watch the condition of the motions, and of the water passed by the child. If there is difficulty in passing water, the infant should be placed with its hips in a basinful of hot water, which will give relief, and this should always be done if no water is passed for twelve hours. If a child is held out at regular intervals, beginning at the age of about two months, napkins can usually be left off at six months. If the water is strong-smelling or thick, plenty of barley water should be given to drink, and a great mistake which people make in infant feeding is to think that milk is sufficient for both meat and drink. Little children want a drink of plain water once or twice a day after the first two months of life.

One of the most important guides to a child's health is its weight. The weight of an infant at birth varies from six to ten, or even twelve, pounds. **Weight.** But infants which, when born, weigh as little as three and a half pounds may grow up into perfectly strong and healthy men and women if they receive proper attention. The following table gives the average height and weight from birth to twelve months.

AGE.	HEIGHT.	WEIGHT.
Birth.	20½ inches.	7 pounds.
1 month.	20½ "	7½ "
2 months.	21 "	9½ "
3 "	22 "	11 "
4 "	23 "	12½ "
5 "	23½ "	14 "
6 "	24 "	15 "
7 "	24½ "	16 "
8 "	25 "	17 "
9 "	25½ "	18 "
10 "	26 "	19 "
11 "	26½ "	20 "
12 "	27 "	21 "

In the first three days of life there is always a little loss of weight, but at the end of the seventh day the child should be as heavy as at birth. Mere weight in a child may sometimes be due to over-feeding, and really a sign of ill-health rather than of good health, but if the muscles are firm, the eyes bright, the lips red, the tongue red and clean, and the inside of the eye-lids a good deep pink, the child is healthy.

When the baby is born it is not necessary for it to have anything to take for the first four hours. Even if the mother is not able to nurse it for

Feeding. eight or ten hours after birth it will come to no harm, but after the first two hours, when the mother has rested a little, the baby should be put to the breasts every hour or two so as to stimulate their action. No artificial food of any kind should be given until it is quite certain that the mother will not be able to nurse. The first milk which comes in the breasts is nature's aperient, and the old-fashioned plan of giving an infant castor oil, sugar, and

water, or butter and sugar, to relax its bowels, is a most injurious one, and should certainly be abandoned. Every mother who is not absolutely an invalid, who is free from hereditary disease, and who has milk sufficient in quantity and up to the standard in quality, should consider it her imperative duty to nurse her baby. It is too much the fashion nowadays for mothers to think that they are not strong enough to nurse the babies, and fashionable physicians are apt to encourage this idea in order to please their patients, but even quite delicate women often make excellent nurses if they are careful as to their own diet.

A nursing mother should lead a calm and regular existence. She should take plenty of milk and infants' foods, abstain from alcohol

Mother's Food, etc. and tea, and drink plenty of barley water. Her chief

meal should be in the middle of the day, and she should abstain from coarse green vegetables, new potatoes, skins and seeds of fruit, and all root vegetables, as these are apt to cause flatulency. A good diet for a nursing mother is, for breakfast porridge or hominy, followed by fish or egg, brown bread and butter, and milk just flavoured with coffee or cocoa made with milk; at 11.30, milk and barley water, beef tea with toast or a biscuit; dinner, fish meat, plainly-cooked vegetables, milk pudding and fruit; 6 p.m., a cup of cocoa with dry toast and butter, egg or fish; 9.30, cupful of infants' food made with milk. If a mother is able to nurse her child even for a few weeks, the child benefits by it, but if she is strong and the milk supply is good, as shown by the thriving of the infant, she should continue till the end of the ninth month, beginning at about seven months to supplement her milk with one or two meals a day of some suitable infants' food, or of prepared cows' milk.

If the mother is unable to nurse, it is necessary that the food should be adapted to the requirements of the infant's digestive organs. It

Artificial Foods. must be remembered that the child has no teeth, no ptyalin in

the saliva, so that starch in any form cannot be digested, that the stomach is small and not muscular, and that the organs are only slightly active, and that the activity of the liver and glands of the bowels is low. There is much to be said against the custom of giving a wet nurse so popular in France, but human milk may be simulated so exactly that a wet nurse is quite unnecessary. The usual substitute for human milk is cow's milk, which contains one-third less sugar of milk, a little less cream, and thrice as much casein or curd as human milk does. It therefore requires considerable modification to make it suitable as a diet for human infants. The chief mistake in giving cows' milk to young infants is simply to dilute it with water, and sweeten it with cane sugar. This does not make a proper food, as although we decrease the quantity of casein by diluting it in this way, we also still further lessen the already deficient cream, the sugar which is necessary to the growth of the bones, and the sugar of milk which is required as a heat former. Cane sugar, or, worse still, beet sugar, does not properly supply the place of sugar of milk, as in the stomach it causes an acetic acid fermentation, which gives rise to flatulence, colic, and other digestive troubles. Sugar of milk is the natural sweetening agent, extracted from its milk, and contains no nutritive as well as the foregoing elements, while it forms lactic acid similar to the natural acids of the stomach.

To make an excellent imitation of human milk, take one quart of milk, allow it to stand, skim off the cream, and place in a separate jug. Then

Imitation Human Milk. take half the milk, curdle it with rennet, strain through muslin so as to remove the curd, and add the

which comes through and the whole of the cream to the remaining half of the milk. Sugar of milk previously dissolved in a little hot water should be added in the proportion of two teaspoonfuls to each pint. The following diet may be given to an infant at birth:—

Cream 1 teaspoonful
 Whey 3 teaspoonfuls
 Hard water 3 teaspoonfuls
 Milk sugar 1 teaspoonful

For one week meal to be given every two hours, from 2 a.m. to 11 p.m., and once or twice during the night. The infant can take about twelve fluid ounces of food daily. From the second week to the sixth, give for each meal:

Milk	1 tablespoonful
Cream	3 teaspoonfuls
Milk sugar	1 teaspoonful
Water	2 tablespoonfuls
seventeen ounces in the twenty-four hours. From the sixth week, for the next fortnight, give	
Milk	2½ tablespoonfuls
Cream	1 tablespoonful
Milk sugar	1 teaspoonful
Water	2½ tablespoonfuls
From the ninth week to the sixth month, give	
Milk	5 tablespoonfuls
Cream	1 tablespoonful
Milk sugar	1 teaspoonful
Water	2½ tablespoonfuls

During the sixth month gradually increase the quantity of milk to nine tablespoonfuls, leaving the other ingredients the same. Barley water may with advantage often be substituted for plain water. In the seventh month some of the infant's food may be added, or baked flour, which is made by filling an earthenware jar with flour (seconds, not Vienna flour), pressing it down tightly into the jar, and then baking, uncovered, in a slow oven, until the flour is of a light golden brown tint. It may be kept in the same jar, a little being scraped out as required; or, if preferred, the whole may be scraped out after baking, but if this is done, it must be kept in tightly-corked bottles so as to exclude the air and keep it perfectly dry. At first, one teaspoonful of the baked flour, boiled for a few minutes in the milk and water, may be given to the meal, and later on, two teaspoonfuls may be given. Before the first teeth appear, no starch in any form may be given. During the eighth and ninth months the quantity of milk may be increased to thirteen tablespoonfuls to each meal, the other ingredients remaining the same; and after nine months, rusk, thoroughly well boiled bread and milk, beaten up with a fork, may be added. After the beginning of the tenth month, cows' milk may be entirely undiluted, and up to the end of the first year it forms a sufficient diet, with the gradual addition of rusks or bread and milk as I have suggested, and the yolk of an egg, lightly boiled, and given with stale bread buttered, beef tea, mutton broth, or veal broth, in change for the midday meal. Junket and custard puddings may be given to babies who can digest them well.

The quantities of food taken at different ages are based on the actual measurements of the infant's stomach and its digestive

Quantities of Food. capacity. Thus, from the first to the sixth week, the child should take from one and a half to two ounces every two and a half hours; from the sixth to the twelfth week, from three to four ounces every three hours; and from that time about the same quantity up till about the sixth month, when from five to five and a half ounces should be given every three hours; at six months, six ounces, and gradually increasing up to ten months, when eight ounces should be given, the interval being still three hours during the day, but perhaps only one or two meals being given during the night. Some foolish mothers feed an infant whenever it cries, and this is the way to ruin any digestion. Regularity in feeding must be maintained, but a child should not be waked to be fed if it is in good health. If very weak, so that it might die from exhaustion during sleep, it is necessary to wake it in order to feed it during the night. Infants' food should always be given at the temperature of the blood, about ninety-nine degrees Fahrenheit. Catarrh of the stomach often arises from giving the bottle too hot or too cold.

The shape of the bottle is most important, as it should be such that it can be easily cleansed in every part. The test is directly on the

Feeding Bottles. neck of the bottle are the best, and long tubes, owing to the difficulty of cleaning

them, are a fruitful source of infantile disease. When not in use, the bottles should be kept in a basin of water containing borax.

The temperature of the lying-in-room should not be kept too warm, or both baby and mother suffer. From 60° to 65° Fahr. would seem to be about the **Sleep.** right temperature, but draughts or cold must be avoided. An infant, if healthy, will sleep a great part of its time without any undue coaxing to that condition. On no account accustom the baby to being rocked to sleep. It is unnatural. The sleep that comes about in its proper course is calm and refreshing; the sleep induced by rocking is fitful and restless. And when the child is asleep do not trouble too much about protecting its head; let it have free breathing, and keep away from its face all clothing accessories that would be likely to touch its skin and irritate it. Also be careful to keep it from disturbing noises; a child awakened by a sudden shock is often seriously affected for a long time.

Next to feeding, the most important matter is certainly the clothing of an infant. Until recent years

the clothing was most irrational and **Clothing.** insanitary, long binders tightly wound round the body, hindering the growth and development of the internal organs, stiff starched cotton garments chafing the delicate skin, and the way in which the clothes were cut, so as to expose the neck and arms, causing all kinds of diseases of the respiratory organs. The chief points to be insisted upon are that clothes ought to be made (1) to cover every part of the body alike, (2) to rest upon the collar bones, so that the arms shall be quite free, (3) to be short and light, so that the child can move its legs quite freely, (4) every garment should be made of wool, which gives the maximum of warmth with the minimum of weight, allows the skin to perspire, and is absorbent of perspiration, (5) that the garments should be as few in number and as simple in construction as possible, (6) that none of the clothes should be gathered in at the waist, lest the weight should be hung from the shoulders. By this system which has now been largely adopted, the child should have next its body a little knitted woollen vest with long sleeves, made to open and fold over the back; a binder, which can be made by splitting a yard of flannel in three. The binder should not be hemmed or embroidered in any way, as the raw edge of the flannel will not chafe in the way that stitches would do. It should also wear a blanket or barrowcoat, made to reach to the throat, and gored in such a way as to give sufficient width round the bottom and allow freedom to the limbs. This should fold over at the back and tie, and the bottom should be pinned up with safety pins so as to keep the legs and feet warm. The robe should have long sleeves, should be made into a little yoke so as to fasten neatly round the neck, and should be about twenty-eight inches long, and twenty three inches wide at the bottom so as to give a circumference of forty-six inches, and allow freedom for kicking. With this system of clothing, the perilous time of short-coating is avoided, and no change should be made in the dress until the infant begins to attempt to stand. Then by putting tucks in the robe and blanket a short dress may be made. As soon as it is not necessary to pin the blanket over at the bottom, little woollen booties should be worn, but these should be knitted or crocheted long enough to protect the legs entirely, and with square toes. The night gown is made similarly to the robe, and buttoned over at the bottom like a pillow case to avoid the infant exposing its limbs by kicking the best-clothing off. The complete layette consists of three binders made as above described, six vests, four blankets, four night or monthly gowns, two day gowns, which may be embroidered and made very pretty by the addition of lace, four piches, and two head fannels. As soon as baby is put into shoes, which is generally not necessary before the age of ten months, great care should be taken that they give plenty of room for the little growing feet, are extremely wide, and that a size larger be got so as not to appear to be tight for the baby's foot. For outdoor garments at first a large white shawl is the best. Long and heavy

cloaks are injurious, but when the baby begins to move its arms about, a jacket with a small cape, cut as long as the robe, but large enough to allow for growth in the body, should be substituted. The narrow cape may be edged with lace if required for ornament. Baby boys as well as baby girls ought to wear hoods out of doors, as it is a notable fact that baby boys suffer much more from earache and catarrhal diseases of the ear than little girls, simply because the girls wear hoods while the boys wear hats which expose the ears, as the ear-pieces put on the hoods generally slip out of place and are useless. The wearing of hats during the early years of life also causes the ears of boys to be disfigured throughout life much more frequently than the ears of girls are, as the hood keeps the ear flat against the head in its proper position. If carelessly put on, of course, the ears may easily be doubled forward by hat or hood, and so be permanently disfigured. All clothing for young children should preferably be white and be changed frequently, as it becomes saturated with the emanations from the skin as well as soiled with external dirt.

The skin is always giving off waste and poisonous matters from the blood, and it is for this reason that frequent ablution is necessary. Some **Washing.** babies, however, suffer from too frequent washing, and the custom of giving two baths daily is responsible for many cases of eczema. The child should be washed all over once daily with water blood-warm, *i.e.*, about 98° Fahrenheit, and tested with a thermometer, and the soap should be very carefully chosen. That recommended by Sir Erasmus Wilson, president of the Royal College of Surgeons, and by Mr. Startin, senior surgeon to the Hospital for Diseases of the Skin, is Pears' Transparent Soap, which, good as it is, is also very economical, considering the quality and the length of time that a tablet lasts. It is specially adapted for nursery use and the most delicate skins. Ordinary violet powders are sometimes dangerous, and have been found to contain arsenic, but Messrs. Pears make a special violet powder from the purest ingredients which bears the guarantee of their well-known name, so in purchasing it is best always to ask for Pears' Violet Powder. It is put up in a neat tin with perforated lid, most convenient for dusting over the skin. Pears' Precipitated Fuller's Earth should find a place in every baby's basket, as it is healing to the skin and most useful to prevent chafings and excoriations.

A word must be said in protest against the custom of using go-carts for young infants. All kinds of deformities and disease may arise through these.

Perambulators v. Go-carts. The baby muscles not being sufficiently strong to support the body in an upright position. Also, by coming too near the ground the child breathes in all kinds of impurities from the dust. The infant should lie down in a comfortable perambulator, or a mail cart in which it can be covered in away from all draughts, until it struggles up into a sitting position on its own account. Nature indicates when a child is strong enough to sit up and when it is strong enough to walk, and to teach it to do those things prematurely is extremely harmful. All kinds of "baby walkers," go-carts, and the like are therefore to be condemned. A child will drag itself up by some article of furniture, and stand, as soon as it is strong enough to do so. Many of the deformities which one sees among the poor are due to mothers vicing with each other as to how young they can make their infants walk. It is better for a child to have straight legs and not walk till it is eighteen months, than walk at ten months and be bandy for the rest of its life.

Storms of discussion have raged round this subject, and many people refuse to regard vaccination as a formidable disease.

Vaccination. pox, and look upon vaccination itself as a serious danger to a child's health. So widely has this view spread that since the passing of the Act permitting exemption in cases of conscientious objection this privilege has been largely taken advantage of, the exemptious having risen from 53,828 in 1906, being five per cent. of the children born, to

37 per cent. in 1914. The adherents of compulsory vaccination maintain, however, that this relaxation has led to an increase of small-pox cases in recent years, and the subject is the cause of much controversy at the present time. Where exemption is claimed it is necessary for the parent or person having custody of the child to make a statutory declaration before a commissioner for oaths or one justice of the peace, stating that a conscientious objection exists, or that the child is in ill health, and within seven days thereafter the statutory declaration (which requires no stamp) must be delivered to the Vaccination officer for the district. But in the ordinary course a child should be vaccinated before the age of six months. For the sake of the child, however, it is desirable to have it done at three months, so that a perfect recovery may be made before the beginning of teething; but if the infant is suffering in any way from ill-health, especially from skin trouble or eruption, the vaccination should be postponed, which may be done by obtaining a doctor's certificate or a form supplied by the medical officer of health for the district, and returned to him. Emulsified calf lymph is the best form to use, and the easiest method of vaccination is to cleanse the portion of the limb, put a little vaccine on the skin, and scratch the surface with a lancet or damping needle, previously rendered aseptic by passing it through the flame of a spirit lamp. No blood should be drawn, and four scratches should be made. In the case of little girls the vaccination should be done on the outer side of the calf of the left leg, where the resulting marks will not disfigure, and it is better to do so even in the case of boys, for when the long-sleeved clothing is adopted as advised here, it is much easier to vaccinate on the leg. A vaccination pad should be tied round the leg as soon as matter begins to form in the little swelling. These swellings should not be punctured, but should be allowed to dry up, and while the child is feverish the diet should consist of whey or milk and barley water, with a little fluid magnesia to keep the bowels well open.

Teething is a natural process to which young and inexperienced mothers look forward almost with dread, simply because every trouble of illness incidental to this period of infantile life—troubles generally caused by improper feeding and ignorance—are set down to teething. Children who are nursed by their mothers, or brought up on the artificial plan here indicated, generally cut their teeth so easily that the mother hardly knows when the process takes place, but those who are brought up in a haphazard manner, especially those to whom starchy foods are given, suffer very much, and very often die of convulsions, which are really not due to the teething but to improper feeding. The rudimentary teeth exist at birth in a soft pulpy form, and while they are hardening, the embryo teeth are pushed forward, exert a slight pressure on the soft parts above, which really dissolve away as the teeth advance, and leave very little so-called "cutting" to be done. For the satisfactory process of teething the three essentials are: (1) a sufficient quantity of time; (2) a system capable of assimilating this and using it where it is needed; and (3) that the gums shall not offer undue resistance to the teeth. When all these things are satisfactory, no other evidence of teething is generally given than an increased flow of saliva, the desire to have the gums rubbed, or to bite on a hard substance, and the appearance of the little sharp white points.

There is great variation in the time for cutting the first teeth. In some cases they appear as early as four or five months, while

Time of Cutting Teeth. in others their advent is delayed until about the end of the first year, but as a rule the process begins at about the sixth month of life. Delay in teething is not always a sign of ill-health, as in some very strong children the muscular development of the gums is so great that it somewhat impedes the teething, as, for example, in one case a child will run about before he has cut a tooth, or in another case although at ten months no teeth had appeared, in the next month six were cut without any trouble. Mothers generally

think that there is a fixed order for the appearance of the teeth, but there is no absolute rule, and it is not of the least consequence which teeth are cut first. Generally, the two lower front teeth are the first to appear, followed by the upper ones which correspond.

If the bones seem well formed, the gums are hot and swollen and tender to the touch, with a gritty, whitish-looking line along the centre part of the top, there is probably too much muscular resistance to the appearance of the teeth, and if the points can be felt quite near the top, the gums should certainly be lanced. When the mouth is feverish and painful, a corner of handkerchief dipped in cold water may be given to the baby to suck, or a piece of ice wrapped in fine muslin will give great relief. Plenty of barley water should be given to drink and the mouth must be kept scrupulously clean with water in which borax is dissolved. The bowels should be regulated. If there is slight diarrhoea under such conditions, and the motions do not exceed four during the twenty-four hours, nothing should be done to stop it; but if the child is constipated an aperient of fluid magnesia is best, and two motions should be ensured during the twenty-four hours. If, on the other hand, diarrhoea is excessive, the milk may be mixed with arrowroot water or rice water to which a few drops of brandy may be added. In extreme diarrhoea milk foods must be stopped entirely, and the infant should be fed on equal parts of white of egg and tepid water alternately with beef essence, and have rice water or arrowroot water to drink. These may be made by soaking two teaspoonfuls of either Patna rice or arrowroot in enough cold water to cover it for half an hour, pour off any water then remaining, and add a pint of cold water. Boil this down to rather more than half the quantity.

Do not rub the gums. The habit of "rubbing through" the teeth with a wedding ring or thimble increases the pain, and is apt to cause inflammation by the article in question not being properly aseptic. Lancing is free from this danger and really much less painful.

If a child seems fat and fleshy, and the division between the bones of the head (which should be nearly closed at one year) remains un-

Soft Head Bones. duly open, while the head perspires at night, lime salts are not being properly assimilated, and sometimes they are not supplied in sufficient quantity. A tablespoonful of lime water in such cases may be added to the bottle three times a day, or if the child is being brought up on the breast, three grains of phosphate of lime may be given twice a day in a little water, and cod-liver oil may be added to the dietary. Where a proper amount of cream is given, as indicated above, however, such cases are practically unknown.

Exercise is necessary for a child's health, and must be provided for, according to weather and other conditions, almost from the first. When a

Exercise. fortnight old it should begin to be taken out into the open air, if the weather be warm, for half an hour twice a day, and in cold weather should be walked about with in arms in a room. The outside temperature should be 60° Fahr. or higher to permit of a very young baby being taken out; but if the weather be again outdoors airing for it, it must still be given its regular quantum of exercise; that is, it should be wrapped in a light, warm

shawl, taken into a room of slightly lower temperature than the one it is nursed in, and carried about. Children of ten months or so may be allowed to kick or fling and creep about the floor amongst a few toys for a while every day, but care should be taken to guard them against draughts from beneath the door or from windows. If a child's legs show signs of weakness it should not be encouraged to try to walk until well over a year old.

Don't expect too much of the baby in the way of "taking notice." Ordinarily, a baby begins to notice objects when from six weeks

"Taking Notice." to two months old, but the mother and the other children, if there are any, are impatient to attract the newcomer's attention, and often tease its eyesight for a little indication of recognition before nature has quite prepared it for the test. The best way is to wait until the baby begins to take notice of its own accord. Then day by day it will grow more observant, and presently begin to recognise its mother and the people about it. Considering that the brain of a newly-born baby is about 14 per cent. of the weight of its entire frame, while the brain of a grown person is but 2.37 per cent. of the weight of the body, some idea may be formed of the danger of putting too great a strain upon the mental power which even "eye-notice" entails on a very young child. Excitement and shock should be carefully avoided.

The development of an infant's senses is naturally slow. Its hearing is the sense that is quickly developed,

the banging of a door, the shouting of other children, often causing quite a shock to the nerves of the child. It is not for some few months, however, that the baby is able to tell from which direction a sound proceeds, or to differentiate between one sound and another. The sense of taste comes early, the distinction between what is sweet and what is not being present almost from the first, but the opportunity of exercising this sense is naturally limited until the teeth arrive, and with them a larger experience of food varieties. The senses of smell and touch are also late in development from similar causes. But sense-development is so much a matter of brain power and of physical health that no hard and fast statements are possible in regard to the different stages of progression. Speech manifests itself but little, even with the most forward children, before they are a year old. Any sounds they utter previous to that age are little more than parrot cries, though not without meaning to those who know how to interpret baby-language. Some children develop their senses very quickly, others very slowly, and it is not always to those of precocious development that the full mental expansion which should come with later years is assured.

If the mother watches the various symptoms of her child's life, studies the excellent literature on the subject which is now freely published, and does not hesitate to call in a doctor when the child's temperature reaches over 100 degrees as tested by a clinical thermometer (the use of which every mother should understand), the dangers of the first year of life will be reduced to an absolute minimum and the baby be started on its career with a sound constitution, which is the best capital his parents can bestow upon it.

PEARS'
of
DICTIONARY
BUSINESS.

Pears' Dictionary of Business

Being a Dictionary of Subjects, Words, and Phrases, relating to Trade, Commerce, Shipping, Finance, and Law.

Abandonment, a marine insurance term indicating that a shipowner abandons his rights in a ship that has been so damaged as not to be worth his recovering or re-instating, and applies to cargo as well as vessel. In these circumstances, the owner assigns his interest to the underwriters, who realise what they can and pay the owner the full amount for which he was insured.

Above Par, a price above nominal value.

Acceptance. A bill of exchange becomes an acceptance when being presented to the person upon whom it is drawn he accepts the responsibility of discharging it by writing across the face of it the word "accepted," with the addition of words indicating at what bank the bill is payable, and appending the signature of himself, his firm, or his company.

Acceptance for Honour, is when a bill of exchange is taken up by some person other than the drawee for the protection of the honour of the nominal acceptor.

Acceptance General is the term applied to bills of exchange that are accepted without any variation from the conditions on which they have been drawn.

Acceptance, Qualified or Special, is when the drawee or payer of a bill of exchange accepts responsibility for part only of the sum mentioned in the bill, or varies it in some other particular.

Accommodation Bill is a bill of exchange accepted by one person or firm for the accommodation of another person or firm, as a matter of convenience or friendship, without the acceptor having received any consideration, an act which practically amounts to a suretyship.

Accountable Receipt is a receipt for money or goods in respect of which the giver of the receipt is subsequently accountable; for example, a pawn ticket.

Accountants are men whose special business it is to prepare, investigate, and audit accounts, and the leading members of the profession are either members of the Institute of Chartered Accountants or the Incorporated Society of Accountants and Auditors, admission to which is obtainable only on passing an examination. There is nothing to prevent anyone setting up as an accountant, however, though the bulk of the accountancy business of the country is in the hands of certificated men, who frequently fill official positions as trustees, receivers, etc.

Active Bonds are bonds bearing a fixed rate of interest payable in full from the date of issue, and include most bonds negotiable on the Stock Exchange.

Act of Bankruptcy. Among the things that constitute acts of bankruptcy on the part of a debtor may be mentioned the following:—Leaving the country, or remaining out of it, or keeping out of the way of creditors for the purpose of delaying or defeating them; assigning property for the benefit of creditors; making fraudulent gift or transfer; fraudulently preferring one creditor to another; filing a declaration of inability to meet obligations; giving creditors notice of intention to suspend; having goods seized by the sheriff; or failing to satisfy a judgment

before the expiration of a bankruptcy notice served upon him.

Act of God, any event beyond human prevention or foreseeing, such as shipwreck, earthquake, lightning, &c., loss in respect of which cannot be enforced unless expressly provided for.

Actuary, an expert statistician whose duties are chiefly concerned with matters of insurance, banking, trusts, &c.

Adjudication Order. The order of Court declaring the bankruptcy of an insolvent debtor and investing his property in a trustee.

Adjustment. A term used in marine insurance, signifying the determination of varying interests in an adventure by the process of average, a work that is usually done by professional "average adjusters."

Advance Freight. An advance payment for freight of sea-carried goods, payable on shipment, and not recoverable in case of loss of goods in transit.

Advance Note. A note given by the master of a ship to a seaman on his signing engagement agreement. If the agreement be made in any port within the United Kingdom the amount advanced must not exceed a month's wages; but if the engagement be made at a foreign port this restriction does not apply.

Adventure, Bill of. A document declaring that goods shipped in the name of the signer are the property of another, whose risk they are, the signer being only liable for what the goods realise.

Advice. Any notification of a business transaction, apprising an agent, correspondent, or customer that a certain thing has been done. This is an important matter of daily detail, the neglect of which may lead to serious consequences. Thus, in the neglect of the advice of a bill of exchange, the bill may be dishonoured "for want of advice."

Affreightment. The hire contract to carry goods by ship, and often included in the bill of lading or charter party.

After Sight. A phrase indicating that the period for which a bill is drawn does not begin to run until presented for acceptance by the drawee.

Agenda. A list of matters to be transacted or discussed at a meeting.

Alien. Any foreign subject who resides in this country and has not been naturalised. He is prohibited from owning or having shares in any British ship and from holding any parliamentary, municipal, or other public office. After a five years' residence an alien can take out letters of naturalisation through the Home Office, the fees in connection with the matter amounting to about £6.

Allowance, a taxing-master's certificate of allowance of costs in a solicitor's bill that has been before him for taxation.

Allonge, a slip of paper attached to a Bill of Exchange to provide space for additional endorsements when the back of the bill has already been filled up.

Allotment, the allotting of shares, stock, or bonds in a company. Since 1901, no allotment of shares can be made unless the minimum subscription mentioned

in the memorandum or articles of association and in the prospectus, as that upon which the directors would proceed to allotment, has been subscribed, and the sum payable on application has been received by the company, or the entire share capital has been subscribed and paid for, conditions which must be carried out within forty days of the first issue of the prospectus, otherwise all moneys received on share account must be returned.

Allotment Note is a document signed by a seaman, authorising payment by his employers of a portion of his wages (not exceeding one half) for a certain voyage, to a relative or bank specified.

All Rights Reserved, a printed intimation in any book or literary work, notifying that the owner of the copyright has legally protected his rights against infringement.

All-Round Price, a price that covers all charges usually treated as trade extras. (See *Overhead Price*.)

Ancient Lights are rights of outlook, light and air, enjoyed by a property owner over adjoining land. Such a right is obtained either by uninterrupted enjoyment for twenty years, or by written authority, and once legally established cannot be upset, no building being permissible that would seriously interfere with the privilege.

Annuity is a payment of an annual sum to an annuitant for a term of years or for life, or to a succession of annuitants in perpetuity. Annuities are of many kinds, and granted under varying conditions. An annuity may be secured by the payment to an assurance company of certain premiums. Terminable annuities, that is, such as cease after the lapse of a specified period, yield a larger sum per annum than life or perpetual annuities, as they deal with a fixed principal sum returnable with interest within the specified term. Deferred annuities do not come into force until a certain time has elapsed or certain contingencies have arisen. Annuities for life are based upon the same principle as that which governs the granting of an ordinary insurance policy—the expectation of life—and are regulated by tables based on general mortality averages.

Ante-date, to give a date prior to that on which it is written, to any cheque, bill, or other document.

Appraiser, a valuer of property, who pays £2 a year for his license, and is liable to a penalty of £50 for acting without one. No examination is necessary for an appraiser. There is a valuation duty payable on all appraisements. (See *Stamp Duties in Office Compendium* section.)

Apprentice, one who contracts to serve another in a trade or calling for a specified term, in return for being taught the "art and mystery" of such trade or calling. Anyone over the age of seven is competent to bind himself apprentice, the father alone being unable to effect the apprenticeship, although usually made a party to the "indentures." An apprenticeship expires (1) by effluxion of time, (2) by the coming of age of the apprentice, (3) by the death of master or apprentice, (4) by mutual consent of the parties, (5) by the bankruptcy of the master. A stamp duty of ss. 6d. is chargeable on an apprenticeship indenture, whether a premium be paid or not.

Arbitrage, a term used in exchange operations and applied to the calculation of simultaneous values in respect of the stocks of different markets, and the equalising of prices by compensating deals, setting out the cheapness of one market with the dearthness of another.

Arbitration, a method of settling a dispute by a reference to disinterested parties, frequently resorted to in order to avoid law suits, and sometimes, where technical or other special difficulties present themselves, recommended by a court of law. Disputes between employers and employed are often settled by arbitration.

Arbitration of Exchange is the calculation entailed when a merchant having money to remit to one country finds it a saving to remit through another country because of the rate of exchange being more favourable in the latter. It is called simple arbitration when only one intermediate place is dealt with, and compound arbitration if more than one be concerned.

Articles of Association are the rules and regulations detailing the scope and method of conducting the business of a limited company. They must be printed in consecutively numbered paragraphs, and are supplementary to the Memorandum of Association, the terms of which they must not exceed.

Assets are property of any kind available towards the discharge of a testator's, intestate's, or debtor's liabilities.

Assign, a legal and trade term applied to the making over of goods, money, or property of any kind to another.

Assignee, the person to whom anything is assigned.

Assignment, a document of transfer of land, personal property, or rights. *Chattel in action*, such as debts, can be assigned and sued for by the assignee on the following conditions: (1) that the assignment is absolute and not simply by way of charge, (2) that the deed is in writing and signed by the assignor, and (3) that the debtor receives notice of the assignment.

"A" Stock, a railway or other company's deferred stock bearing this designation.

At Sight, a form of notification written on bills or notes denoting that they are payable on demand, without allowance of days of grace.

Attachment, a legal term applying to the seizure of a person's goods or personal effects under process of law, and has special reference to the writ of attachment authorising such seizure.

Attestation is the formal witnessing of the signing of any deed or document and the subscribing of the witness's name in proof thereof. Two witnesses, who are not interested, are required to a will, and they must append their signatures at the request and in the presence of the testator and in the presence of each other.

Attorney, Power of, a document authorising the person to whom it is given to act in all respects as the grantor of the power, in relation to matters specified in the document. Where the power is general it applies to everything in which the grantor is interested, when special it applies to specific matters, such as the power to sign cheques, bills, transfers, deeds, to receive moneys, to effect sales, etc.

Auction is a public sale at which goods or properties are offered for sale by an auctioneer, and sold to the highest bidders when the sale is without reserve.

Auctioneer, a person licensed to sell goods or property by public auction. He is usually paid by commission, and his license costs him £10 a year. In respect of goods seized under distraint, or for sales under the Small Debts Acts, the person selling need not be a qualified auctioneer.

Auditor, the person who carries out an audit of accounts. He is liable to be proceeded against for damages if by his omission or neglect any loss arises. It is no part of his duty, however, to criticise the actions of principals, or to concern himself with the prudence or imprudence of transactions disclosed by the books. His chief duty is to ascertain the true financial position of the business and get out a balance sheet in which this is accurately set forth. The employment of auditors is compulsory in regard to the accounts of most public bodies and companies, but no director or officer of a company may hold the position of auditor.

Average, a marine insurance term applying to loss or damage at sea. It may refer to *particular average*, a contribution by underwriters for part loss or damage; or *general average*, a combined contribution on ship, freight, and cargo for damage and expenses incurred for the common good. Average in the ordinary commercial sense indicates "a mean proportional between two or more figures."

Average Bond, a bond given by the consignees of cargo to the owner or captain of a ship which has sustained a general average loss, agreeing to pay the consignees' proportion of average when ascertained.

Average Clause, the clause in a marine insurance policy excluding certain articles from average unless general, and denaring others free from average if under a specified percentage.

Average Stater or Adjuster, one who possesses expert knowledge in matters of marine insurance, whose business it is to make out statements of averages for the underwriters in regard to claims for loss.

Award, the decision of an arbitrator or arbitrators, or their umpire, on matters in dispute that may have been referred to them. Unless otherwise stated, or by consent for extension of time, an award must be delivered within three months of the arbitration. An award requires a *ros* stamp. Prior to 1906 ad valorem duties were charged, ranging from *grl.* to 35%.

Back Bond, a bond whereby a property owner converts a possession into a trusteeship, in consideration of a loan, his original position being restored on repayment.

Backed Note, a receiving note, endorsed by a shipbroker, authorising goods to be transferred from barge to shipboard.

Back Freight occurs when from causes beyond a captain's control goods cannot be landed at the point of destination, and have to be conveyed back to the place of shipment, freightage thus becoming chargeable against the owner for the return voyage.

Backing a Bill, the act of accepting a bill of exchange by writing across its face the usual form of acceptance and signing it, a term usually applied to the accepting of accommodation bills.

Backwardation is the condition existing when stock can be bought cheaper as a matter of account than for cash. The term is likewise used in respect of the rate of interest paid for "carrying over" a bargain from one fortnightly account to the next instead of closing the transaction.

Bail is the security given for the release, pending formal trial, of a person charged with some offence.

Bailment is the delivery of goods by one person to another for a specific use or purpose, a condition which arises when goods are lent, or pawned, let on hire, entrusted for conveyance, or in temporary custody for repair or alteration. The owner is called the bailor, and the person to whom the goods are delivered is the bailee, who is responsible for their safety and their re-delivery on the conditions on which the goods were deposited being fulfilled.

Balance of Trade, a form of expression in general use to denote the difference between the aggregate value of the imports and of the exports of a country.

Balance Sheet, a summary of the accounts of a business, setting forth in grouped totals on the debit side the amount of capital employed, and the debts and liabilities, and on the credit side the entire assets, including cash, stock-in-trade, property, plant, buildings, and debts owing.

Bank Holidays are otherwise working days on which banks are closed in addition to Good Friday and Christmas Day, and are now largely observed as general holidays. They are (in England and Ireland) Easter Monday, Whit Monday, the first Monday in August, and the day after Christmas Day, or if the day after Christmas should be a Sunday, the following day. In Scotland the Bank Holidays are New Year's Day, the first Monday in May and August, and Christmas Day and the next day. Bank Holidays were the result of an Act introduced by Sir John Lubbock (Lord Avebury).

Banking, as we understand the term to-day, did not exist in England before the time of Charles I., and was adopted first as a protective measure against the risks of royal confiscation, and next for purposes of commercial exchange. In Venice, Barcelona, and Amsterdam, banking systems of a crude kind had been in operation long before this, and London goldsmiths and merchants like Gresham had performed certain banking functions, but it was not until 1694, when the Bank of England was established, for the better handling of the National Debt, that banking in its modern significance was established. Other banks were soon afterwards formed, but were prohibited in 1697; gradually, however, the prohibition was evaded, and in the course of the 18th century many private banks were started in London and the chief provincial centres. This progress notwithstanding, it was not until the London and Westminster

Bank began operations in 1833 that any institution existed as a bank of deposit only. The Bank Charter Act of 1844, which introduced a limiting of note issues and other salutary regulations, did much to improve the general banking conditions. Occasionally, in times of commercial panic, many banks failed, and as under the old joint-stock companies' law each shareholder was liable for all indebtedness, at these periods many people were ruined. The passing of the Limited Liability Companies Act in 1862, however, enabled banking as well as other companies to restrict the liabilities of their shareholders to the amount of their nominal holdings. Banking is now of enormous range. In addition to the ordinary banks, there are savings banks all over the country, and the Post Office Savings Bank, established in 1861, has deposited with it between one and two hundred millions sterling.

Bank Bill, a bill of exchange drawn by one bank upon another.

Bank of Deposit, a bank receiving money at a specified rate of interest, deposits being only withdrawable after a prescribed previous notice has been given. The bank, being thus guarded against emergency calls, is able to invest its moneys more favourably than ordinary banks, and to pay higher interest.

Bank of Issue, a bank authorised to issue its own notes payable to bearer on demand. In London and within a radius of sixty-five miles, the Bank of England is the only bank of issue, except certain banks established prior to May, 1844, which share the sixty-five miles monopoly. Shareholders are liable for the amount of notes outstanding in case of a bank's failure, even though the bank has been registered under the limited liability acts. No new bank of issue can now be formed.

Banks, Joint Stock, banks whose capital is subscribed by shareholders, and with very few exceptions, limited liability companies, the liability, however, not extending to note issue.

Bank Notes are promissory notes of a bank, payable to bearer on demand. In England the minimum sum for which a note may be issued is £5, in Scotland and Ireland £1. Only Bank of England notes are legal tender. Country banknotes can be re-issued after payment, but Bank of England notes are never re-issued.

Bank Post Bills came into use in 1738 as a protection against mail robberies. The Bank of England issues them for sums of not less than £10 or more than £1,000 payable seven days after sight, on the amount being deposited, and without charge, the seven days' interest being the bank's remuneration. These bills are not subject to days of grace.

Bank, Private, a bank carried on by one or more persons, not exceeding ten, in partnership. These banks, however, are now few, none having been established in recent years, and such as were private are for the most part amalgamated with banks of limited liability.

Bank Rate, the rate at which the Bank of England grants loans or discounts bills, and declares at each weekly meeting of the directors, mainly influenced by the gold supply and demand.

Bank Return, the weekly report of the financial condition of the Bank of England, issued every Thursday.

Bank Stock, strictly the Bank of England's banking capital, the rate of interest being regulated according to the Bank's profits. The capital of other banks is also called bank stock.

Bankers' Cheques, a cheque drawn by one bank on another.

Bankers' Clearing House was established to enable bankers to realise the value of the cheques and bills in their hands for collection from other bankers without the trouble of separate presentation at different banks. The Clearing House is managed by a Committee, and although dating back to 1775, it only since 1857 that the present convenient system of clearing has been in operation. Well over twelve thousand millions' worth a year is now cleared.

Bankrupt, one who is insolvent and unable to pay his debts, but only of legal application when a person has been declared bankrupt by a court of law.

Bargain and Sale, a legal term usually referring to a contract for the sale of real property, but also applicable to contracts for the transfer of personal property, although for the latter the word *general use* is assignment.

Barratry is an offence committed by mariners, and may consist of either deserting or sinking a ship, embezzling cargo, doing any other act whereby the shipowner is injured.

"Bear," a Stock Exchange operator interested in bringing down the price of certain stock and operating with that object. It applies more particularly to one who has sold stock which he does not possess and desires to induce a fall in price prior to the next settling day, so that he may make a profit by buying at a lower price than the one he agreed to sell at.

Bear Account, an account of "bearing" transactions, the selling entries representing a greater amount of stock than the "bear" can deliver and often entailing "backwardation" payments to effect a "carrying over" to the next account.

Bearer. The term "or bearer," or "to bearer," on bills or cheques, denotes that the person holding the same has the same right in respect of it as the person specifically mentioned.

Bearer Bond, a bond for money loaned made payable to the bearer or holder of it.

Below Par. When prices are under nominal value they are quoted as so much "below par."

Beneficial Interest, a right to enjoy or derive profit from property which may be legally vested in another. For example, a mortgagee has legal though not actual possession, the mortgagor, who retains practical ownership so long as he carries out the conditions of the mortgage, enjoying the beneficial interest.

Bequest, a gift of personal property left by will.

Bid, a price offered at an auction or other sale, withdrawable at any time before it has been acknowledged by the auctioneer or seller.

Bill Broker, one who buys and sells bills of exchange or promissory notes, selling bills drawn on foreign countries, and buying bills for remitters to those countries. A close knowledge of matters influencing rates of exchange is necessary to the carrying on of this class of business, which is distinct from that of bill-discounting.

Bill for Acceptance, a bill of exchange forwarded by a trader for acceptance by the person on whom it is drawn.

Bill of Credit, a letter authorising the advance of money to a specified person, and undertaking, or implying the obligation, on the part of the writer, to reimburse the person acting on the letter.

Bill of Entry, a written description of goods entered at the Custom House, either for intended exportation or importation.

Bill of Exchange, a written order by one person to another desiring him to pay a person or firm named, or bearer, a certain sum at a certain time. An inland bill of exchange is drawn and payable in the United Kingdom; a foreign bill of exchange is payable abroad. Before it is legally completed a bill of exchange must be signed both by the drawer and the acceptor—the latter being the person who accepts the liability of discharging the bill on the day it falls due.

Bill of Health, a certificate signed by a consul or other official delivered to masters of ships when they leave places, showing (in the case of a *clean* bill of health) that, when the ship sailed, no infectious disorder was known to exist at the port of sailing. A *suspected* or *touching* bill implies that there were rumours of infection; and a *quarantine* bill, or the absence of a clean bill, indicates that the ship sailed from an infected place.

Bill of Lading, a receipt from a ship's captain to the shipper undertaking to deliver goods—on payment of freight—to some person whose name is expressed or endorsed thereon by the shipper.

Bill of Sale, a deed or document designed to furnish evidence of the sale of personal property, as, for instance, goods or furniture, when the sale has not been followed by the immediate transference of such chattels to the custody of the purchaser. A bill of sale must be registered within seven days of its execution.

Bill of Sight. In case of an importer not being

able to make out a complete bill of entry he is allowed to sign such a general description as will serve for the time, and on that, which is called a bill of sight, the goods are landed, though not allowed to be delivered before a proper bill of entry is presented.

Bill of Store. Goods of British origin which have been exported to a foreign country can be re-exported within five years without being liable to importation duties, and when that takes place the particulars are entered in what is termed a bill of store.

Bill of Suffrance is an official permit to a ship to proceed from one British port to another, with dutiable articles on board, and trade, without paying Customs duties until landed or placed in a bonded warehouse.

Bill of Lading, a licence to carry stores, for use on a voyage, free of duty.

Bimetallism is an economic theory which seeks to establish that gold and silver should both be kept at a fixed standard.

Blank Acceptance, a term used when the acceptor of a bill of exchange signs the acceptance without naming the amount or when it is drawn, in which it is open to the drawer to insert afterwards any amount up to the limit covered by the stamp.

Blank Bill or Note is one that is drawn without giving the name of a payee.

Blank Credit, a term used to designate a class of bills resembling accommodation bills, drawn for temporary financial convenience, but not representing actual indebtedness.

Blank Indorsement, an indorsement of a bill of exchange or other document, from which the name of the person to whom it is given is omitted, and is payable to bearer.

Blank Transfer, a transfer of stocks or shares, omitting the name of the transferee, often given to bankers as security for money lent on such stocks or shares.

Board of Trade, a department of the British Government, forming a permanent committee of the Privy Council, and presided over by a member of the Cabinet. Its constitution dates from 1780, but the business of the office is wholly controlled by the President. The six departments of the Board of Trade are: (1) Commercial, Labour, and Statistical, established in 1824; (2) Railway, dating from 1845; (3) Marine, in operation since 1851; (4) Finance and General, since 1851; (5) Fisheries and Harbours, since 1866; and (7) Bankruptcy, established in 1883.

Bond, a document under seal engaging to pay a sum of money or carry out some contract or obligation. It is the nature of a mortgage, and becomes void on its obligation being discharged, but although it is usual to insert in the bond, as penalty for non-fulfilment, double the sum actually secured, only the sum really owing, with interest, costs, etc., is recoverable. The Statute of Limitations does not apply to a bond, being a document under seal, until the expiration of twenty years from the accruing of the right to sue Government, Municipal, Railway, Company, and Corporation securities are usually in the form of bonds.

Bonded Debt, the sum owing by a State or Corporation for the repayment of which it has given bonds.

Bonded Goods are goods stored in a bonded warehouse, and not chargeable with duty until required for consumption. The owner is required to enter into a bond to pay the duty on removal of the goods.

Bonded Vaults, the name given to the underground cellars used for storing wines and spirits under the same conditions as already mentioned in respect of Bonded Goods.

Bonded Warehouse, a building set apart for the storage of dutiable goods, the duty on which is not payable until they are removed. The warehouse is in the entire charge of revenue officers.

Bond Note, a note authorising the removal of bonded goods for exportation or to another warehouse, and requiring the signature of a Customs House official.

Bonus an allowance beyond the ordinary dividend of a company, either in the form of extra money payment or by way of allowance in reduction of premium or otherwise.

Book Credits are the credit entries in business

books by which adjustments of finance are enabled to be made with but little passing of cash or notes, on the same principle as banks balance their Clearing House transactions.

Book Debts, the debts recovered in a trader's books in the ordinary course of business. They are assignable, but the assignment must be in writing and must show adequate consideration. Each debtor must also have notice of the debt. In the absence of such notice, payment made to the original creditor is legal.

Bottom, a marine term now applied to a ship generally, though originally only signifying the keel or hull.

Bottomry, the act of mortgaging a ship.

Bottomry Bond, a contract or mortgage by which a ship becomes a pledge for the repayment of money advanced to enable it to proceed to its destination, and only recoverable if the ship succeeds in terminating its prescribed voyage satisfactorily. In the case of more than one bottomry bond being given, the last has precedence of realisation, on the ground that the last money advanced secured the completion of the voyage. This kind of contract is not in much use in these days, when ordinary Marine Insurance policies practically cover all requirements.

Bought Notes and **Sold Notes**, otherwise **Contract Notes**, are notes which traders exchange with each other, giving particulars of sale and purchase transactions as entered into between them.

Bounties are premiums paid by a Government to persons engaged in producing or exporting certain goods to encourage industry or favour competition.

Brand, a distinguishing name, design, or trademark used for putting on goods, or on cases in which they are enclosed, to define ownership, class, or quality.

British Ship, a vessel owned exclusively by British subjects, or by a corporation or company established in British dominions according to British laws, and registered as a British ship, except in cases of vessels of small tonnage.

Broker is an agent acting for others in buying or selling goods, and carrying out the arrangements between buyers and sellers without having the actual possession of the goods. He must not act in his own name.

Brokerage, the commission, percentage, or fees paid to the broker for his work in connection with any business carried through by him.

Brokers' Contract Notes are notes signed by brokers after effecting a sale or purchase of goods, and sent to those for whom they have been acting. The note to the seller is called the "sold note," that to the buyer the "bought note." They are identical as to particulars.

Brokers' Returns, particulars sent to ship-brokers, setting forth all the items of the cargo of a ship.

"B" Stock, the title of certain preference, railway, or other stock.

Bubbles, the name given to fanciful and sensational financial schemes without substantial foundation, engineered for speculative purposes, and ending in disaster. The most notable example in this country was the South Sea Bubble.

Bucket Shops are the offices of outside brokers who are not members of the Stock Exchange, and are unable themselves to carry out Stock Exchange transactions, but get members to act for them.

"Bull" one who buys, or contracts to buy, shares in the expectation of a rise in price, and consequently realising of profit on them by selling day.

Bull Account refers to the account of a "bull" who, finding himself with more stock than he can settle for, pays what is called "contango" for the privilege of having the account "carried over" to the next settlement.

Burden, a ship's carrying capacity reckoned by tonnage.

Buyers Over, a term indicating buyers are in excess of sellers.

Buying In. If within ten days of a stipulated date a seller on the London Exchange fails to deliver securities bought the buyer may buy in against the seller, the latter becoming liable for all expenses incurred. The time allowed, however, varies at different exchanges.

Bye-Laws are special rules and regulations made by any company or corporation for the carrying on of its affairs, but they must neither contravene the powers conferred by Parliament nor the laws of the land.

Call, an instalment due on shares not fully paid, payable according to the terms of the prospectus or Articles of Association of the company. The term is also used in respect of the option of exercising a call to buy or sell specified securities during a certain period and at a certain price.

Called Bond, a bond concerning which a notice or "call" has been sent out that it will be redeemed on a date named.

Call Money, money lent to bill-brokers and repayable on demand or "call."

Call of More, or "option to double," is the privilege to double the amount of one's present buying at a future-named date on the same terms.

Cancelling is the act of rendering inoperative any bill, note, cheque, deed, or other document. This is usually done by writing or stamping across the face of the document the word "cancelled," or by perforation or obliteration of the signatures.

Capital is either fixed or circulating. The former is money spent in land, houses, factories, workshops, machinery, or other things necessary for the carrying on of business, and not of a nature to be sold or exchanged. Circulating capital is money provided for the purchase of raw material, the remuneration of employees, and other working expenses in the ordinary course of business, and returns to the owner, along with a certain profit, as the products of the workmen are realised. Thus this capital is kept circulating, and unless the whole of the profit made be taken out of the business, will be continually increasing. In a general way, the term capital signifies the money and money-value invested in a business undertaking. The actual capital of a limited liability company is the amount that its shareholders may have subscribed for the carrying on of the undertaking. The term, however, has a varied application. Thus the full sum named as capital in the Memorandum of Association is called the "nominal," "authorised," or "registered" capital, while the sum represented by the shares actually taken up is called the "subscribed capital," the portion remaining unpaid or uncalled up being styled "unpaid" or "uncalled" capital. The principal sum of a loan is also called "capital."

Capitalisation is the act of providing money to be used as capital in a commercial or other undertaking.

Carat, a term used in ascertaining the value of gold and precious stones. In connection with gold, it represents the proportion of pure gold contained in any gold alloy, and for this purpose the metal is divided into 24 parts. Thus 24 carats indicates pure gold, and any lesser number of carats shows the proportion of gold contained in the alloy. As used by jewellers in weighing precious stones, a carat represents 3½ Troy grains. **Carrier**, any person or company engaged to convey goods for hire in the regular way of business. Thus railway companies are common carriers so far as concerns their carriage of goods, but the term does not apply in respect of the carriage of passengers. So long as goods are in the custody of a carrier, he is responsible for their safety, being exempted, however, when damage results by the "act of God," from the "act of the King's enemies," or from "inherent vice," that is, natural deterioration, bad packing, etc.

Carrying Over, a term used to signify the postponement of the settlement of an account over the proper settling day to the next, for which accommodation the speculator has to pay backwardation and other charges. (See **Backwardation** and **Contango**.)

Cart Note, the official note authorising the transfer of drabable goods from one bonded warehouse to another, or from wharf ship to bonded warehouse.

Case of Need, a conditional endorsement on a bill of exchange, naming an additional person, firm, or company, to the acceptor to apply to "in case of need" to take the bill up. The usual form is "In case of need apply to Messrs _____."

Cash, generally speaking, consists of coin, notes, bills, or other documents, that can be immediately con-

verted into cash; but its strict legal significance does not extend beyond coin and Bank of England notes.

Cash Bonus, a life insurance term, applied to a bonus paid in cash to the insurer, and not otherwise dealt with.

Casting Vote, the vote given by a chairman or president of a meeting when the votes of those present are equal. The vote may be his only vote, or, as is usually the case, it may be in addition to his vote as an ordinary member. It is a matter that is generally provided for in the Articles of Association of a company, and is not a right that exists at common law.

Caution Money is money deposited as security for the fulfilment of a contract or obligation.

Certificate, an authorised or official document certifying title, right, or verification, respecting its subject-matter.

Certificated Bankrupt, one who, having passed his examination in bankruptcy to the satisfaction of the court, is granted his certificate of discharge from his existing debts.

Certification of Shares is when shares represented by one certificate are sold in batches, and the company takes the certificate, and certifies on the transfer that the shares therein enumerated are in their custody. If only a part of the holding be sold, a "Balance Certificate" is given to the owner for what remains unsold.

Certificate of Damage, a dock certificate testifying that certain goods on being landed from shipboard are in a damaged condition. Without this the importer cannot recover compensation.

Certificate of Incorporation, a certificate issued by the Registrar of Joint Stock Companies, after the registration of a limited liability company.

Certificate of Origin, a document authoritatively indicating the place of origin of the goods, materials, or manufactures mentioned therein.

Certified Transfer, a transfer testifying that the certificate of the shares mentioned therein has been lodged with the company, and necessary only when a portion of the shares has been sold.

Cessio Bonorum, a Scotch process of law, involving an assignment for the benefit of creditors, after which the debtor is free to resume trading; although after-acquired property becomes liable to seizure until the full extent of the claims against him is satisfied.

Cestui que Trust, one entitled in trust to the income and profits, which he is bound to apply according to the terms of the trust.

Chamber of Commerce, an association of merchants, manufacturers, traders, and others, organised for promoting the interests of trade; and exercising a very beneficial influence in obtaining and spreading statistical information, aiding commercial legislation, and otherwise.

Charter, a government or Crown grant of concessions, powers, or privileges to individuals, companies, or institutions. Such an organisation does not come under the Companies Acts.

Charterer, one who charters the whole or part of a ship under an agreement of charter-party.

Charter-Party, a hiring contract whereby the owner of a ship grants to another person or persons the right of using the whole or part of a ship for a specified voyage or period for the carriage of goods.

Chattels consist of movable property such as furniture and household goods generally, as distinct from fixtures or land.

Cheque is an order on a bank for the payment of a specified sum of money, on presentation, to the person named in the document, or to the bearer. It does not require endorsing when made out to bearer, but must be endorsed when payable to order. Each cheque requires a penny stamp in this country. A banker is liable for loss on a forged cheque unless he can prove carelessness on the part of the drawer. (See **Cheques Crossed**.)

Cheques Crossed. A cheque is crossed for protection. The crossing is usually done by the drawer, who writes " & Co." between two parallel transverse lines across the face of the cheque, after which the cheque can only be realised by being passed

through a bank. The simple " & Co." crossing is called "general"; when the name of a particular bank is added it is called "special." (See also **Not Negotiable**.)

Cheque to Bearer, a cheque payable to the person holding it without requiring endorsement. The wording "or Bearer" after the name of the payee is sufficient, but if the cheque be crossed it must be paid into a bank.

Cheque to Order is one having the words "or Order" printed or written upon its face, to follow the name of the person in whose favour it is drawn, who must endorse the cheque before payment can be obtained. If crossed it must be paid into a bank.

Chose in Action, a commercial-law term denoting a thing in respect of which one has a right of action as distinct from a thing in actual possession. For example, mortgages, bonds, warrants, policies of insurance, and debts. Such rights are now assignable; prior to 1893 they were not.

Chose in Possession, a thing in actual ownership, such as goods and chattels.

Circular Notes, not less in amount than £50, are issued by banks to persons about to travel abroad, to obviate carrying large sums on the person. According to requirements, the bank forwards what is called "a letter of indication" to correspondents at stated places at which the traveller will stop, directing the payment to him of any sum up to a specified limit. Each letter is signed both by the bank and the payee, to prevent personation or forgery.

Clearance may mean (1) a Custom House permit for a vessel to sail out of a port and signifying that all dues have been satisfied; or (2) the same privilege in regard to goods, showing that all local obligations have been disposed of.

Clearance Inwards refers to ships that have arrived at port and discharged their cargo.

Clearance Outwards refers to vessels ready for leaving port.

Clearing a Bill, providing cash to satisfy a bill of exchange.

Clearing Bank is a bank affiliated with the London Bankers' Clearing House.

Clearing House, Bankers', the house through which bankers pass the bills and cheques they hold on other banks by a mutual arrangement, which enables daily settlements to be made on the balance of total sums, thus obviating delays, and greatly facilitating banking transactions. The representatives of each bank attend at the house at 10.30 each morning, and present to each other lists of obligations on behalf of their banks. This interchange having been effected, the clerks return to their respective banks. Three other clearings, at which the same process is repeated, take place during the day. Notification of any cheques or bills that a bank decides not to honour must be given before 4.45. By this system, transactions to the value of many millions are effected each day without the passing of a single note or coin.

Clearing House, Railways, an association of which nearly all the railways of England and Scotland are members, and utilised for settling the accounts of the various companies having running powers over each other's lines. It also deals with various matters connected with the general relations and working of the different railways.

Clearing House, Stock Exchange, deals with Bonds and Shares on much the same principle as that of the Bankers' Clearing House in respect of cheques and bills.

Collated Telegram, a telegram that the sender has repeated to secure accuracy, and for which he pays an extra charge.

Collateral Security is additional security given by a debtor to further safeguard the satisfying of moneys advanced.

Commission, allowance made to agents and others for effecting sales or carrying out business transactions.

Commission Agent, one who sells or buys goods for another, and receives by way of remuneration a commission or percentage upon the amount involved in each transaction.

Committee of Inspection, a committee of creditors appointed by the whole body of creditors to supervise the winding-up of the affairs of a bankrupt or of a company.

Commodatum, a Latin term referring to a loan on condition that the actual things lent shall be returned.

Compounding with Creditors, an agreement whereby creditors agree to accept, and a debtor undertakes to pay, or secure payment of, a certain sum in each £ in full settlement of indebtedness.

Compulsory Winding-up is the winding-up of a company's affairs by the order and under the supervision of the Court of Bankruptcy.

Concession, a special privilege granted by a government, corporation, or other authority to concessionaires, and may include land grants, mining or building rights, powers to construct railways, and the like.

Conditional Advance Note, a note given by the master of a ship to a seaman, undertaking to pay to the seaman's order, a certain sum after a certain time, on condition that the seaman goes with and serves on the ship. (See **Advance Note**.)

Conditions of Sale, the regulations under which land, houses, or goods are put up for sale by public auction, and by which purchasers are bound. It is usual for "particulars and conditions of sale" to be printed and distributed prior to or at the sale.

Confirmation, a note appended to a "confirming an order." On being signed by the receiver it constitutes a confirmation of the contract.

Consideration may take the form of a money payment, a delivery of goods, a promise of money payment, or a promise of delivery of goods, or compensation for loss.

Consideration Money on the Stock Exchange is the amount paid by a buyer to a seller when a sub-purchase is probable; however, the sum stated is often not that actually received, the Stamp Act requiring that the consideration money of the sub-purchaser shall be inserted as the sum regulating the ad valorem duty.

Consignment Note, a form required to be filled up for the despatching of goods by rail or other common carrier.

Consol Certificates are issued by the Bank of England and certify that the holder is entitled to £50 or some multiple of £50 in the Consolidated Three per cent. Annuities.

Consolidated Fund consists of several separate government funds, pledged for the payment of the interest of the National Debt, cost of Army and Navy maintenance, government salaries, &c.

Consols (Consolidated Annuities) comprise the greater portion of the National Debt. They were originally (1751) made to bear interest at three per cent. but the rate has been two and a half per cent. since 1903.

Constructive Total Loss is a marine insurance loss entitling the insured to payment of the full amount for which he is insured on abandonment of his ship and its contents. (See **Abandonment**.)

Consular Invoices are invoices of goods requiring to be declared before and certified by the consul of a country to which they are being exported. Such invoices are only required in respect of goods for the chief South American States, Portugal, and the United States, and as regards the last named country only when the goods exceed £50 in value.

Contango, a cant term of the Stock Exchange denoting the charge made for carrying over a transaction from one settling day to the next.

Contango Day, otherwise "continuation day," or "making-up day," is the second day before settling day, when arrangements are made as to carrying over transactions.

Contingent Liability, a liability which may be discharged without any liability accruing. Thus, the liability of a banker who accepts bills for a customer of substantial position is not likely to accrue.

Contract, any binding agreement between two or more parties, and implying both an agreement and an obligation. There must be offer and acceptance, legal capacity to contract, consideration, and genuineness, otherwise the contract is voidable.

Contract Note, a sharebroker's written particulars of a contract made by him for a client.

Contributories, persons liable to contribute to the amount unpaid on their shares in a limited company in case of the company being wound up. In case of the realisation from existing shareholders being insufficient to discharge the company's indebtedness, those who have been shareholders within a year of the winding up are liable to be called upon as contributories.

Convertible Paper Currency is one that can be converted into cash on demand, as a Bank of England note.

Convertible Securities are such as are always marketable and convertible into money. Consols, railway stock, and exchequer bills, for example.

Co-operation, as the term is generally employed, signifies the union of persons of small means for the purpose of buying necessaries and other things at the lowest rates, and sharing any profits that may arise in proportion to the capital or labour invested. The first co-operative store in England was started at Rochdale in 1844. The movement was eagerly taken up in the great manufacturing districts, and to-day it embraces a vast organisation. There are now some 1,600 co-operative societies comprising considerably over 2,000,000 members. The two wholesale co-operative societies effect sales to the amount of about £30,000,000 per annum.

Copyright, the right of ownership in a literary or art production, vested in an author or producer or his assigns for the life of the author and seven years after, or the full period of forty-two years after publication, whichever shall be the longer.

Cost, signifies the total sum necessary to be paid to cover the expense of making, producing, and remunerating services, in respect of any article or commodity.

Cost and Freight, a term used in respect of goods sold at a price covering cost and carriage.

Cost Book Plan indicates a method of accounts used by mining companies composed of what are called "adventurers," who, by arrangement with a landowner, search for mineral, and in case of discovering it take a lease by which the owner receives a share of the output, and the rest of the yield is the profit of the operators. All particulars are entered in the "Cost Book," and a shareholder can withdraw at any time so long as he has discharged his proportion of the liabilities.

Council Draft is a negotiable instrument drawn by the Secretary for India upon the Indian Council and payable at the Bank of England.

Country Clearing, the clearing of cheques and bills paid into country banks, through the London Clearing House by the London agents of the banks.

Country Notes, the bank notes of any bank of issue other than the Bank of England.

Coupon, a detachable portion of a ticket or document; in banking and business, a warrant or certificate for the payment of interest or dividends; in travelling, one of a series of tickets issued to cover separate portions of a journey; and as used in periodicals and newspapers, a form entitling the possessor who fills it in, to engage in some competition.

Course of Exchange, the price given in one country for a specified sum in the currency of another country.

Cover, a deposit of cash or securities ensuring the depositor against loss in stock exchange or other operations carried out on the depositor's behalf.

Credit Letter of, a letter from a bank, firm, or one person to another, authorising payment to a third person named of a specified sum, for which the sender assumes responsibility.

Credit Note is an acknowledgment, by a seller, of defects in a thing he has sold, and forms a note of credit for a certain reduction of charge in consequence of the defects.

Cum Dividend, a transaction that carries with it the right to receive the dividend then falling due.

Cum Drawing, a sale of bonds, carrying with it the right of any profit to accrue from the ensuing drawing.

Cum New. The right is sometimes accorded to shareholders of a company to have allotted to them

new shares that are being issued on more favourable terms than they are offered at to the general public. Shares sold at this period are said to be "cum new," carrying the right of the special terms of purchase.

Cumulative Preference Shares are shares the dividend on which is a fixed rate and in default of payment in one year, or in any number of years, the amount accumulates until payment can be made. Such dividends take priority over other dividends, though not over debenture interest. (See **Preference Shares**.)

Currency by Tale was the old form of currency of which the Greek obolus may be taken as an example, admitting of being passed from one to another by simple counting, without other test of value.

Currency by Weight, the primitive form of paying by weight of metal, before the introduction of coinage.

Currency Bonds are bonds guaranteeing the repayment of principal and interest in the currency of the country of their issue.

Currency Principle, a phrase used to describe a method adopted by some banks of maintaining an exact equality between the amount of credit and the amount of specie, relying on commission charges for their profits.

Current Account, the amount of money a person has deposited at a bank, and on which he can draw from or add to as may be desired, no interest being chargeable on either side.

Customs are duties levied on goods imported or exported, and have been charged since Anglo-Saxon days, varying greatly from period to period according to necessity, kindly greed or special emergency. Since Free Trade was practically established in this country customs charges have been greatly restricted, still even now the revenue from customs reaches something like thirty-five millions sterling in Great Britain.

Customs Bills of Entry, a daily list issued by the Customs' authorities to subscribers, including a full list of ships' reports, inward, with their cargoes, also of ships sailing with other particulars.

Customs Debenture, a certificate in respect of exported goods entitled to drawback, for duty already paid, which the debenture enables the owner to get refunded.

Customs Declaration, a form that has to be filled up and signed by one who sends goods abroad, stating the nature, weight, and value of the goods.

Customs Duties are duties payable on imported goods, the main articles of which, as regards this country, are tea, coffee, cocoa, dried fruits, tobacco, cigars, wines, spirits, and cordials. The number of dutiable articles has been reduced from some 1,200 articles, in 1840 to about 50 at the present time.

Customs Entry, a statement of particulars of the nature, value, and weight, of imported or exported goods furnished to the customs officials.

Dandy Note, formerly a custom house order sanctioning the transfer of goods from warehouse. Term now obsolete. (See **Shipping Bill and Note**.)

Day to Day Loans, money borrowed for a day at a specified rate of interest, and renewable from day to day by mutual agreement.

Dead Account, the account of a deceased person, or an account that has ceased to be operative.

Dead Freight, the amount charged for empty space to one who having chartered to load a full cargo falls short of requirement.

Dead Loans are loans unpaid at the specified date, or for which no day of repayment has been stipulated.

Dead Reckoning, a nautical term used in calculating a ship's position at sea from the distance shown by the log only, with allowances for leeway, etc., without astronomical observations.

Dead Rent, a term applied to a lease of mining rights, the rent of which it is stipulated shall be paid whether operations are carried on or not.

Dead Security, a term denoting industrial securities on which there can be no realisation unless the properties are sold.

Dead Weight, cargo that pays freightage according to weight, irrespective of measurements, such as iron, coal, etc.

Debenture, a document, or certificate, signed by a public officer, corporation, or company, acknowledging

ing indebtedness for money lent and guaranteed repayment with interest.

Debenture Bonds are the bonds of a government, company, or corporation, engaging to repay a specified borrowed sum, with interest, at a time named, the interest being payable periodically by coupon until the bond matures and is paid off.

Debenture Stock differs from debenture bonds in that it is usually irredeemable. The principal sum is registered in the owner's name, and the interest, which takes priority of dividends, is paid by warrant to the owner's order.

Debit Note is a note giving particulars of an allowance claimed in respect of defective or damaged goods.

Debt, a term generally applied to an amount due or payable from one person to another in return for money, services, goods, or other obligation.

Decimal System is based on a unit of 10, and for purposes of calculation is much simpler than the English system. It is in operation in France and other European countries, also in the United States.

Deer Cargo is cargo carried on deck in regard to which no liability for damage attaches, unless there is an express stipulation, to that effect.

Deed is a written or printed document under hand and seal. It must be signed in the presence of a witness or witnesses, must bear a seal, and must have formal "delivery"—that is, the signer must either give constructive delivery by placing his finger on the seal and saying, "I deliver this as my act and deed," or actual delivery by handing over the deed. Without "delivery" the deed is inoperative.

Deed of Arrangement, a deed of assignment or composition, whereby a debtor conveys property effects, goods, or debts to a trustee or trustees for realisation and distribution among his creditors on the terms specified. Such a deed requires registration as a bill of sale within seven days of execution.

Deed of Insolvency is a deed providing for the realisation and winding-up of an insolvent debtor's affairs by trustees or inspectors.

Deferred Annuities are such as do not come into effect until such a specified later period as agreed upon. Such annuities are purchasable at any post office. In case of death before a deferred annuity begins, the purchase-money is given to the purchaser.

Deferred Bonds are bonds issued by a government, corporation, or company, entitling the holder to a gradually increasing rate of dividend or interest, until a fixed maximum rate is reached, when they become converted into ordinary bonds.

Deferred Stock or Shares are such as do not rank for dividend until after the ordinary, preference, and guarantee dividends have been provided for.

Deficiency, the allowance for shrinkage, by evaporation or otherwise, in dutiable goods during their storage in bond.

Deficiency Bills represent temporary loans made by the Bank of England to the Government.

Delivery Order, an order, signed by the owner of specified goods, addressed to any person or official having charge of them, and requesting delivery of them to the person named in the order. It is negotiable to the extent that it can be placed with a banker to secure any advances he may make on the goods. Since 1906 there has been no stamp duty on a Delivery Order.

Demand Draft, a bill of exchange payable on demand.

Demonetise is the act of depriving coin of the quality of legal tender.

Demurrage, a charge to which the charterer of a ship is liable by neglecting to load or unload within the time named in the charter-party. The term is also used in connection with delays in removing goods after being conveyed to the station of destination.

Deposits, in the commercial sense, comprise deposits of money for employment in business, deposits of negotiable securities with a banker for safety, deposits of similar documents as security for loans, deposits of money or bills in a bank in the ordinary course of business on current account, and deposits of sums at interest.

Deposit Account, deposits of money with bankers withdrawable only on giving a specified previous notice.

Deposit Receipt, bankers' receipt for moneys deposited, specifying the terms of the deposit.

Deposit Warrants acknowledging the deposit of articles as security for loans are of two kinds, special and general. The former includes bills of lading, pawn tickets, dock warrants, and applies to actual goods returnable on repayment of loans, &c.; while the latter does not apply to specific goods so much as to values.

Derelict, a vessel abandoned by its crew, and in respect of which salvage accrues to those who save it, or what it contains.

Despatch Money is the opposite of demurrage, being money allowed by a shipowner when a charterer loads or unloads in less time than originally specified.

Despatch, the note sent by the Customs with dutiable goods, and necessary to be produced at the place of destination.

Deviation, a marine insurance term indicating an alteration of course from that set down in the policy, a departure which, unless made for avoiding perils, annuls the risk of the underwriters.

Differences are payments representing the difference between contract prices and market prices, occurring between speculators who buy and sell apart from the wish to possess. Contracts to pay differences cannot be enforced.

Discount is a deduction which is customary to be made for prepayment or prompt payment of money due. Bank discount is an advance charge reckoned at simple interest rates on the amount of a note or bill.

Discounting a Bill, the act of purchasing at a certain deduction or discount, a bill of exchange, and the right to realise upon it at maturity. The rate of discount varies with circumstances—the credit of the parties liable on the bill, the current rate of interest, and other matters.

Discretionary Order, an order from a client to a broker to purchase stock up to a certain amount at discretion.

Dishonour, the refusal to accept a bill of exchange on presentation for acceptance, or to pay it at maturity.

Dissolution of Partnership, the discontinuance of a partnership from any legal cause, a notice of which must be inserted in the *London Gazette*, and also specially intimated by letter or notice to all with whom the firm have had dealings.

Distress or Distraint, a legal term implying the act of distraining for non-payment of rent, a remedy that dates back to Anglo-Saxon times, but does not obtain in the United States, and in some other countries. Distresses for rent have to be made by day on the premises rented, but if the chattels have been fraudulently taken away, they can be followed and seized at anytime within 30 days.

Dividend, a periodical payment of interest on an investment; and when declared upon the capital of a company undertaking it must be out of profits alone. A dividend may also be a composition or part payment in respect of a claim on the estate of a bankrupt, or a company in liquidation.

Dividend Warrants are written orders to a banker authorising the payment of dividends, and are negotiable.

Docket, a summary copy of any decree; a brief list or label; derived from dock, to cartail.

Dock Warrant, which must bear a *gd.* stamp, is an instrument issued by a dock-owner or company in favour of a person specified by the owner of goods warehoused in dock, and entitles such person to take possession of the goods. Advances on dock warrants are readily made by bankers.

Document Bills are bills of exchange attached to the bills of lading, policies, or invoices, in respect of which they have been given. Should a bill of this class be dishonoured, the holder can claim on the document.

Domiciled is a term applied to a bill of exchange made payable at a particular place.

Donatio Mortis Causa, a donation in prospect of death.

Draft, a written order for payment of money; a bill of exchange.

Drawback, the amount returned by the Customs on exported goods which have already paid duty, and payable only to the actual owner of the goods.

Drawee, the person on whom a bill is drawn, his liability on which does not come into force until he signs and accepts it, after which he is the acceptor.

Drawer, the person who draws a bill, who in case of dishonour is liable to the holder or any indorser who is compelled to pay it.

Drawer's Bonds are bonds of a class in respect of which periodical drawings are made, such drawing being by lots, the holders of such as are drawn being entitled to payment in full, after which time, if unredeemed, no interest is paid.

Dutch Auction, the "cheap-jack" method of starting the sale of an article at a price, and gradually lowering it to an amount at which a sale is effected, or the article withdrawn.

Duties are taxes levied upon goods, commodities, or manufactures. In the case of imported or exported goods these duties are called customs, while duties on home products fall under the head of excise.

Easement, a legal term applied to a privilege enjoyed by any one over another's property, the most familiar example being a right of way.

Ejectment. When a tenant after the termination of his tenancy, either as the result of a notice to quit or otherwise, continues in possession of premises, an action at law can be commenced, and what is called a writ of ejectment issued. If the rent be over £100 a year the action must be in the High Court, otherwise the County Court must be appealed to.

Embargo, a Government order, mostly issued in war time, prohibiting vessels from leaving port, but not applicable in this country to ships carrying wheat.

Emblements are growing crops to which an outgoing tenant has a right if his tenancy terminates before they can be harvested.

Endorsee, the person to whom a bill of exchange passes when made over to him by endorsement.

Endorsement, the signing of one's name on the back of a bill, an act which transfers the right in it to the endorsee.

Endowment Policy is one on which premiums are payable only for a prescribed period, after which the insurer has no other liability, and may either receive the amount for which he is insured, let it remain to accumulate with interest, the whole to be paid at his death, or take an annuity based on the policy value, as may be stipulated in the policy.

Enforced Paper is the "rupee paper" of the Indian Government.

Engross is an ancient mercantile term connected with the idea of monopoly. To engross was to buy up an article in order to increase prices. It also means to write or copy in a hold clear hand.

Entry, particulars of goods imported or exported, supplied for registration at the Customs House, and compulsory whether the goods be liable to duty or not.

Entry for Warehousing, an entry made at the Customs House giving particulars of dutiable goods to be stored on import in a bonded warehouse, and not liable to duty until taken out for consumption.

Equation of Payments, an arithmetical operation determining the date at which a single payment may be made instead of several payments due at various times.

Equitable Mortgage, a charge created on an estate, either by deposit of title deeds or by agreement in writing, which does not as in an ordinary mortgage constitute a transfer of the legal estate.

Errors and Omissions Excepted (*E.E. or E. and O.E.*), when written at the foot of invoices or accounts indicate that they are open to after-correction if any mistakes should be discovered.

Estate Duty is the duty payable upon the value of all property, of which any person may die possessed.

Estoppel, a legal term indicating that a person is barred of a legal remedy because of some former act which precludes him of the right. Estoppel may be either by deed or act.

Estimate, a written statement specifying the

amount of money for which a contracting party will perform certain work or supply certain goods.

Estreat, a certified copy of an original document or record in regard to fines or amercements. The term is also applied to the levying of fines under an estreat.

Ex All, a Stock Exchange term signifying that the stock or shares specified as being sold are sold apart from any dividend, bonus, or profit then due.

Exchange is the giving or receiving of one thing for another; also the name of any building set apart for the meeting of merchants and others for purposes of buying and selling.

Exchequer, which derives its name from the checkered table on which accounts were calculated in early Norman times, is a term connected with the revenues of the Crown. The Court of Exchequer Division existed up to 1881, when it was abolished. In former times it had jurisdiction in all revenue matters. The term Exchequer is now mainly applied to the Governmental department which deals with the public revenues, and is presided over by a Chancellor, who is a Cabinet Minister.

Exchequer Bills, bills issued by the Treasury for sums varying from £100 to £1,000, and bearing interest at the rate current on the day of issue. They are made repayable, at par, in a year from date, but can be renewed annually.

Exchequer Bonds, which are made payable to bearer, are issued by the Treasury for sums borrowed. They are for a specified period (which must not exceed six years), at the expiration of which they are redeemable at par.

Excise Duties are inland taxes imposed on articles of home product for home consumption, or on their manufacture or sale, and were first established in England in 1043.

Ex-Drawing, without drawing, a term used in regard to bonds sold, and indicating that the buyer is not to have any benefit that may accrue from a drawing then taking place.

Execution, a process of court whereby, default having been made in satisfying a judgment, a writ or order of execution is issued authorising the sheriff or bailiff to seize and sell the goods of the debtor, or such portion of them as may be necessary, to discharge debt and costs.

Ex Mero Motu, of one's own action.

Ex-New, not including the right to new stock or shares about to be issued, and for which the shares purchased might entitle their original owner.

Ex Parte, on behalf of, a term used in reference to any proceeding taken by, or concerned with, one party alone, apart from other parties interested.

Expected to Bank, an expression referring to such of a bankrupt's liabilities as may be expected to be entitled to rank for dividend against the estate.

Ex-Ship, a sale of goods on shipboard, all the cost and responsibility of the removal of which falls on the purchaser.

Ex-Warehouse, a sale of goods, the cost of removing which from the warehouse must be borne by the buyer.

Face Value, the nominal value marked on the face of a security—the par value.

Factory and Workshops Act, 1901, is the Act under which all factories and workshops in the United Kingdom are at present regulated. Factories are divided into two classes, textile and non-textile. The Act provides improved regulations as to the sanitary condition of factories and workshops, guards against overcrowding, requires certain things to be done for safety, prescribes who may be employed, and for what number of hours per day or week, etc., and provides an elaborate organisation of inspectors to see the Act enforced.

Fee-Simple, land in absolute ownership, and at the owner's complete disposal.

Fee-Tail, freehold property entailed in a certain line of descent.

Fiduciary Loan, a loan granted without any security being taken.

Fiduciary Note Issue, an issue of bank notes without the provision of a money reserve to meet them,

relying on the confidence of the public and the honour of the bank.

Fine, a sum of money which a legal tribunal, or other properly constituted authority, imposes on a defaulter, transgressor, or trespasser, the payment ordinarily being held to discharge the grievance.

First Class Paper, bills, notes, and other securities given by firms, companies, corporations, or Governments of high position and of undoubted solvency.

First of Exchange, the first of a set of foreign bills of exchange, usually drawn in triplicate. If the first be paid or satisfied, the others fall valueless.

First Open Water, a marine term introduced in charter-parties relating to vessels proceeding to the Baltic ports, and denoting the time when a ship first touches the open sea after the breaking up of the winter ice.

Fixed Capital is money invested in land, buildings, and other property of a more or less permanent nature, such as railways, tramways, factories, etc.

Fixtures are legally such moveable additions to a building or land as when actually secured become part of the freehold. (See also **Tenant's Fixtures and Trade Fixtures**.)

Foaming Point, the temperature at which oil becomes explosive. In the United Kingdom the flash point is 73°.

Floater, a Stock Exchange term referring to what are called Bearer securities, on which loans are readily raised, and as the loans on them are called in by one bank are passed to another, and so on, hence the name "floaters."

Floating Capital is capital which a trader or banker reserves for ordinary business or financial operations and does not appropriate for fixed or permanent investment.

Floating Policy, a marine insurance policy that covers certain specified goods without naming the ship by which they are to be conveyed.

Floating Security, a term used in regard to the security of a limited company, and forming a charge on its assets, but not enforceable unless there is default in payment of principal or interest.

FloTEAM, a legal term applied to goods lost at sea and found floating on the water. FloTEAM does not belong to the finder, but must be delivered up to the rightful owners, or, if no owner appears, becomes forfeit to the Crown. The finder, however, is entitled to a reward proportionate to the value of the goods. (See **JetTEAM**.)

Folio, a term of four different meanings: (1) in bookkeeping it means two pages facing each other; (2) in ordinary legal documents 72 words constitute a folio; (3) in Parliamentary documents there are 90 words to the folio; and (4) in printing the folio is the number of any single page.

For Money, meaning a sale "for money" on the Stock Exchange involving immediate delivery of the securities purchased and payment on receipt, a class of transactions applying specially to Consols.

For the Account, Stock Exchange transactions included in current account for settlement on the next settling day.

Foul Bill, a document given by a Consul or other competent official to the master of a vessel on leaving port, certifying that at the time of clearing the port was infected with contagious disease.

Founders' Shares, are such as are granted to persons concerned in the founding and originating of a company, as compensation for their promotion or other services. They are usually issued tully paid up, and often carry with them special profits and privileges.

Free of all Average, a marine insurance term denoting that in case of partial loss no average, but only in respect of total loss, can be entertained.

Free of Capture and Seizure an insurance term expressing non-liability in case of a ship falling into the hands of a belligerent or other capturing force.

Free of Expense to Ship, a clause throwing all liability for cost of loading or unloading on the charterer.

Free of General Average, a clause in a marine policy absolving the underwriter from general average contributions. (See **"General Average"**.)

Free of Particular Average, a clause defining the insurers non-liability for partial loss, unless the same has been brought about by accident or unavoidable cause.

Free Override, a term indicating that the risk of goods sold is with the buyer after being unshipped.

Free Trade was advocated by Adam Smith in his *Wealth of Nations*, and after a long and bitter agitation, in which Cobden, Bright, Milner Gibson and others actively championed the cause, the principle was legally established in this country by the abolition of the Corn Laws in 1846. By establishing free inter-change of commodities without protective duties, British trade expanded at a wonderful rate during the following three decades, and few were found to favour the old principles of protection. Meanwhile, America, Germany, and other countries were fast building up large industries, and setting up high protective duties against foreign goods. About 1880, in consequence, many manufacturers and merchants in this country began to combine in a Fair Trade organisation, which, however, did not make such headway as to bring about any reversal of Free Trade policy. In May, 1903, Mr. Joseph Chamberlain, who had previously been a staunch Free Trader, advocated a new fiscal policy, in which retaliation by protective duties against such countries as use protection against Britain was proposed. This led to a considerable split in the Unionist party, and Mr. Chamberlain himself resigned his position as a Cabinet Minister in order to have a free hand in urging forward the new movement. Mr. Balfour, the then Prime Minister, declined to avow himself either completely on the side of Mr. Chamberlain or as a Free Trader, and all the Free Trade members of the Ministry thereupon seceded, including the Duke of Devonshire, Lord Balfour of Burleigh, Lord George Hamilton, and Lord Eversley. Since then much discussion has taken place in regard to the fiscal question, and although the verdict of the elections in 1906 seemed to be in favour of Free Trade as a general principle of policy, the agitation for Tariff Reform has increased rather than diminished. Since then both sides of the subject have been actively advocated, and the Unionist party as a whole stands pledged to the principles of Tariff Reform.

Freehold, real estate held in fee simple in perpetuity. (See **Fee Simple**.)

Freight, charges paid for carriage of goods of merchandise by ship; a term still used in the older sense to denote the goods themselves.

Freight Note, statement giving particulars of freight charges.

Freight Release. When goods have been shipped "freight forward," a note of "freight release" showing that all freight charges have been paid must be produced to the master of the ship before they can be taken away.

Funded Debt, the Government's debt in respect of which there is no obligation to pay within a fixed period, or the date of repayment is at some remote date, and taking the form of Consols chiefly.

Funding, the operation whereby a floating debt is converted into stock.

Futures, foreign produce bought for future shipment, and representing speculative operations with a view to "cornering" tactics.

Garnishee, the person on whom a garnishee order is served.

Garnishee Order, an order of court attaching money or goods belonging to a judgment debtor, the object being to prevent such money or goods being handed by the debtor instead of applied for the benefit of his creditors.

Garnishment, notice to a garnishee concerning goods or money, in respect of which a garnishee order has been obtained.

Gazette was the name given to the first news sheet published in Venice about 1536, and named after the coin *gazeta*, which was its price. The term is now in general use, but applied more particularly to publications of an official character, such as the *London Gazette*, which contains Court and Government notifications, lists of public appointments and honours, legal notices and lists of bankrupts. The

London Gazette was first established at Oxford in 1666. There are similar official publications in Edinburgh and Dublin.

Give On, the paying of contango.

Godown, an Oriental storage warehouse.

Gold. (See article on **Gold** in *General Information* section.)

Gold Bonds, bonds payable in gold coin.

Good Delivery, a Stock Exchange term indicating that a security is in proper form and condition.

Goods and Chattels include all kinds of movable property, as well as rights of action, bills, debts, banknotes, bonds, etc.

Goodwill is the intrinsic value of the good repute and custom of an established business.

Grace, Days of, a period of three days allowed by custom of law beyond the fixed day of payment for a bill of exchange or note. Should the last day of grace fall on a Sunday, or other non-business day, the bill or note is due on the preceding day.

Grounding, the charge for space occupied by a ship while in port.

Graving, the cleansing of the bottom of a ship.

Graving Dock, a dock where ships are graved.

Ground Rent, rent payable to the owner of freehold land for the privilege of erecting and maintaining buildings upon it for a specified term of years, after which the buildings become the property of the landowner. The buildings are leasehold property.

Guarantee Fund, a reserve fund set apart to meet possible losses.

Guarantee Society, one which guarantees employers from losses in respect of the defaults, omissions, or malpractices of employees. The guarantee takes the form of an insurance policy, on which an agreed annual premium is paid.

Guaranteed Stock, stock, the interest on which, or the principal, or both, is guaranteed.

Habeas Corpus, the name given to a writ ordering the body of a person under restraint or imprisonment to be brought into court for full inquiry into the legality of the restraint to be made. The first Habeas Corpus Act was passed in 1679, though nominally such a right had existed from Magna Charta, but some of the more despotic kings had disregarded it. In times of public peril the privilege of habeas corpus is sometimes temporarily suspended, many instances occurring in the recent history of Ireland.

Half-Notes. In remitting money, business men sometimes forward half-notes forwarding the other halves on the first being acknowledged. In regard to this practice it is important to know that the property in entire note belongs to the sender until he parts with the second half.

Hall Marks are official marks impressed upon gold and silver articles, testifying to their genuineness and value. The stamping is entrusted to the Goldsmiths' Company of the City of London, at Goldsmiths' Hall, and the marks are the standard of quality, the assay-town's mark, notification of duty paid, date, maker (and sometimes) workman's mark. The term "hall-mark" in common metaphorical use in writing and speech is an indication of quality.

Hammered, a stock-exchange form of proclaiming a defaulter. When a member is unable to meet his engagements, the fact is notified from the rostrum, first of all, by striking three blows upon it with a wooden hammer, which calls the members up. The name of the defaulting member is then given out, and he expelled or temporarily suspended. On paying not less than 6s. 8d. in the £, the defaulter's claim for re-admission will be considered by the committee, and if there are no other charges against him, he may again become a member, but even then he is not discharged from after liability in respect of the balance of his indebtedness.

Haulage, charges for the use of trucks, wagons, or carriages, from one point to another, exclusive of loading and unloading them.

Heavy Stock, a term referring to the stock of railways handling a heavy goods traffic.

Hereditaments may be *corporeal*—as land, or any substantial and permanent property thereto

attached; or unattached, including goods or jewellery; and *incorporeal*, as real charges upon property, the right of user in articles, or offices and privileges issuing out of corporeal holdings. *Incorporeal* hereditaments comprehend franchises, annuities, ways, commons, advowsons, tithes, and the like.

Heritable Bonds are such as include a conveyance of land that comes into operation when the bond itself is not redeemed, or the interest paid, as stipulated.

High Seas are the seas that are open to all, and represent the entire sea-space beyond three miles of the shore.

Hire Purchase, goods obtained on hire which become the absolute property of the hirer on paying the last of the instalments stipulated to be paid by him, but until then he cannot deal with the goods, having no ownership in them. Such goods, however, are not exempt from distraint for rent. If default be made in payment of the instalments the owner has power to repossess himself of the goods.

Holder, one to whom a bill of exchange or cheque has been made over, and who has lawful possession of it for the time being.

Holding Over, the act of refusing to quit possession of premises after the expiration of the term of a tenancy, or of legal notice to quit. A liability for double rent attaches to such action.

Home Consumption, a term denoting (1) goods consumed in the country of their production, or (2) imported goods stored in a bonded warehouse until duty is paid and they are brought into consumption.

Home Use Entry, a document authorising the removal from a bonded warehouse of goods liable to duty on such goods being required for home consumption.

Horse Power, the draught power of a horse, the unit of measurement introduced by Watt for estimating the power of the steam-engine, and defined as 550 foot-pounds per second. The estimate is higher than the average drawing power of the horse justifies, but its use as a working standard is not affected by this.

Hotchpot, a legal term signifying the bringing into common sharing of a specified property, as in the case of a child, who during his father's lifetime has had a portion of estate given to him, being compelled, on the father dying without will, to bring his share into hotchpot to be included in the statutory division ordained for intestates' estates.

Impersonal Accounts are such as relate to things as distinct from people, as goods, cash, etc.

In Advance of Calls, a phrase referring to payments made by shareholders prior to call being made on their shares.

In Ballast. A ship is in ballast when, not having any cargo, she carries some weighty substances for stability.

Income Tax is the personal impost charged on the income of individuals, and was first imposed by Pitt in 1798 to meet the heavy cost of the war with France.

Inconvertible Paper Currency is paper money which cannot be exchanged on demand by the holder for cash to its full nominal value, and, owing to the uncertainty in regard to its realisation, is at a discount in the market.

Indemnity, a formal legal acceptance of responsibility against damage or loss in such circumstances as may be expressed.

Indents are orders from distant countries for goods, specifying particulars and prices, and owing their name to the fact that they were formerly written on forms bearing an indented line, part of which remained with the sender, while the other part was on the order. With the increased facilities now existing, however, there is no special force in an indent beyond that of an ordinary order.

In Forma Pauperis, a special privilege accorded by the English law to suitors, who, being unable by reason of their poverty to pay the costs of legal proceedings, are permitted to have such costs remitted.

Injunction, an order or judgment of court restraining some person or persons from doing certain things which are detrimental to the interests of another or others.

Inscribed Stock is stock in respect of which

holders are simply registered, no certificates being issued to them. No one can deal with such stock except actual holders or persons appointed by the power of attorney of holders.

Insolvency, the condition which marks a man's or a firm's inability to meet full monetary obligations. When a person is in this strait, he can either call his creditors together and endeavour to come to some private arrangement with them, according to the nature of his assets, or he can place himself in the hands of the Bankruptcy Court, which will administer the estate and distribute the assets for the benefit of the creditors.

Inspecting Order, a written order authorising goods in dock, bonded warehouse, or other place, to be shown to the holder.

Insurance, a provision or contract securing against loss by fire, tempest, or other contingency; insuring compensation for accident; allowance during ill-health; or payment of a stipulated sum at death to beneficiaries indicated. Insurances are usually effected with insurance companies, who take the hazard in consideration of annual premiums paid to them by the person insuring. The rates are based on a system of averages.

Intarbores Securities are such as are negotiated simultaneously in different countries, and are dealt in at fixed rates of exchange.

Interest, in its commercial sense, is payment made for the loan or use of money, and is calculated according to a specified rate. Interest is either *simple* or *compound*. When simple interest is paid, the principal sum remains the same; in case of compound interest, each year's interest is added to the principal, and succeeding interest calculations are on the increased amounts.

Interim Dividends are such as are paid on shares before the time of declaring the full dividend.

Interpleader, a form of lawsuit the purpose of which is to decide between rival claimants to property or money. The suit is usually reverted to by the officers of the law when in possession of property of disputed ownership.

Intestacy is the condition supervening on a person possessed of property dying without having made a will. An intestate's real estate devolves upon his heir or heirs; his personal estate goes to his next of kin according to the Statutes of Distribution.

I O U, an informal written and signed acknowledgment of indebtedness, requiring no stamp, and, though not a promissory note, can be sued upon. The letters stand for "I owe you."

Issue of Shares and Loans. Shares are issued by the sending out of certificates in return for subscription payments, and declare the holders entitled to so many shares. A loan issue consists of bonds with a similar declaration.

Jarquer, the principal of the Customs department where all documents relating to import ships are finally cleared, or jarquered.

Jettison, a term in navigation law, signifying cargo thrown into the sea and sunk. Such goods belong to the Crown in default of other claimants. (See *Flotsam*.)

Jettison, a legal term referring to cargo thrown overboard in time of sea-peril to save the ship. The liability to make good property so lost is apportioned according to averages.

Joint Stock Companies may be limited or unlimited, and their capital must be subscribed by more than twenty persons, as with fewer than twenty one subscribers the undertaking is a partnership.

Joint Tenancy, the occupation or possession of land by persons jointly and equally entitled.

Jointure, the property settled on a woman at her marriage forming her separate estate to be enjoyed after the death of her husband.

Journey, the technical name given to fifteen pounds' weight (701 sovereigns) of coined gold, or 60 lbs. weight of coined silver.

Judgment Creditor one who has obtained a court judgment against a debtor.

Judgment Debtor, one against whom a court judgment for payment of debt has been obtained.

Keel, a ship's bottom, the chief foundation timber reaching from stem to stem and holding the whole frame together. In an iron or steel ship, the term signifies the plates that correspond to the keel timbers of a wooden ship.

Keep House, a term applied to a debtor who denies himself to creditors calling at his house. This constitutes an act of bankruptcy.

Kentledge, permanent ship-ballast, and generally consisting of pigs of iron.

Leaches, in commercial law, are acts of negligence or carelessness.

Leagan, floatable goods cast overboard from a sinking ship.

Landing Order, a Customs document authorising the chief officer of a ship, after dues paid, to hand over goods for landing, during which process the walter or searcher examines the goods and finally signs the order as correct.

Larceny in its broad significance means the fraudulent taking away and appropriation of the personal goods of another. Larceny is of two kinds: *simple larceny*, which is theft apart from accompanying aggravation; and *compound larceny*, that which is rendered more serious by being combined with assault, or forced entrance into an enclosed place, such as a house or shop.

Leatage, sand or gravel used for ballasting a ship.

Law Merchant, the mercantile law, which embodies the customs and usages ordinarily sanctioned between merchants and traders, and is recognised as part of the common law of the country.

Law Days are days allowed for loading or unloading ships according to agreement, and date from the time that official permission to load or discharge has been given.

Leakage, an allowance made for losses on liquids by leaking.

Leakage and Breakage, a term of exception sometimes inserted in a charter party or bill of lading and indicating that the shipowner is exempt from liability for any damage of this kind occurring on a voyage, unless caused by negligence of the crew in handling or stowing the goods.

Lease, a letting, or the document setting forth the letting, of lands, tenements, machinery, or other property for a specified consideration and time. A lease for a longer period than three years must be by deed.

Leaseholds, which are personal property, however long the term, are lands or houses held on lease, subject to the payment of ground rent to the freeholder.

Legacy, a gift by will of personal property. There are three classes of legacies: (1) *general*, being payable out of a testator's general assets; (2) *specific*, when comprising a specified part of the testator's property; (3) *demonstrative*, when a certain fund is made liable for the discharge of the legacy; but if the fund has ceased to exist or is inadequate the general estate must supply it.

Legal Day is the whole of the twenty-four hours of a day, from one midnight to the next.

Legal Tender is gold is good in this country to any amount; of Bank of England notes for any sum above £5, except in certain circumstances by the bank itself; silver is legal tender up to 40s.; bronze up to 1s.; farthings up to 6d.

Letter of Allotment, a letter informing an applicant for shares that certain shares have been allotted to him. A stamp duty of 1d. is chargeable on such letters for less than £5, and of 6d. for higher amounts.

Letter of Credence, a letter given by a monarch or other head of State to an ambassador for delivery by the latter to the ruler of the country to which he is sent.

Letter of Indemnity, a letter undertaking to be responsible for any loss or damage sustained in circumstances specified.

Letter of Licence, a document signed by creditors, authorising a debtor or other person to carry on a business for a specified time, and undertaking to abstain from taking proceedings during that time.

Letter of Rescission, a letter sometimes

appended to a letter of allotment, enabling the allottee, by filling up and signing it, to renounce his allotment if he desires to do so.

Letters of Administration, the Probate Court document of authorisation to the next of kin or other representative of a person who has died intestate to administer the estate according to the Statutes of Distribution.

Liabilities by Endorsement are liabilities incurred by the endorsement of bills or other negotiable instruments whereby the endorser becomes responsible for payment should the other parties to the document make default.

Libel, any writing, printed matter, picture or illustration put forth with malicious intent for the purpose of injuring or bringing a person into public ridicule and contempt. An aggrieved person may proceed either by civil action or criminal indictment. A good defence is that the words complained of are true and to the public advantage to be made known. Since 1861 no newspaper proprietor could be criminally prosecuted for libel without the fiat of the Public Prosecutor. A spoken libel is *slander*.

Licence, special permission to do or sell certain specified things, usually such as are liable to excise duty. Licences are required for keeping carriages, dogs, for shooting game, for hawking and peddling, for selling beer, ale, wines and spirits, tobacco, patent medicines, etc. Excise duties in the United Kingdom produce over thirty millions sterling.

Lien, the right by which a person holding personal property of another can retain possession of it until some claim that he has against the original owner is satisfied.

Light Dues are charges levied on ships for the maintenance of lighthouses, beacons, etc., around the coasts.

Limitations, Statute of, passed in the reign of James I. still remains in force, whereby it is laid down that actions for trespass, or debt, or simple contract, cannot be instituted after the lapse of six years from the date of the cause of action; that actions for assault, menace, or imprisonment must be brought within four years; and actions for slander within two years. Actions for the recovery of land must be commenced within twelve years.

Limit, a point of price fixed by a principal, beyond which a broker or agent is restricted from buying or selling.

Limited Liability in regard to companies has been in operation since 1855, and in the case of such undertakings as are registered as "Limited," the liability of shareholders does not extend beyond the paying in of the amount represented by their respective shareholdings. After the passing of this Act limited companies were formed in profusion, and the system was much abused, rendering further restrictive legislation necessary. Many serious company frauds were brought to light from year to year, and in 1907 a fresh Companies Act was passed compelling the publication of such facts and particulars as now renders this class of fraud more difficult of perpetration.

Liquid Assets consist of readily realisable property, such as coins, notes, Consols, and other high-class securities.

Liquidated Damages, an agreed amount of damage in case of breach of contract; or, in an action, the definitely ascertainable amount that may be indubitably due.

Lloyd's, started as a meeting-place for merchants and shipowners at a coffee-house in Abchurch Lane, London, kept by Edward Lloyd, gradually developed into a very powerful association, and since 1774 has had its offices in the Royal Exchange. The members of Lloyd's mostly engage in the business of insuring or "underwriting" ships.

Lloyd's Bonds owe their name to the lawyer who settled the form of them, and are sometimes used by corporations in place of debentures as security for loans.

Lloyd, Austrian, an association of Austrian merchants, founded in 1833 at Trieste on the lines of the British Lloyd's, and owning lines of steamers and interesting itself in literary and scientific affairs.

Lloyd, North German, an important company

owning powerful lines of steamers trading between Germany and all parts of the world.

Lloyd's Policy, a document signed by underwriters at Lloyd's setting forth the terms of the particular insurance effected by it.

Lloyd's Register forms a full record and classification of all British ships, and of foreign ships classed in the register, and is published yearly. The surveyors of Lloyd's make periodical surveys of vessels, and keep a systematised inspection over ships intended for classification. The first class mark for ships is A. Lloyd's Register is now kept in a handsome and spacious building at the top of Lloyd's Avenue in Fenchurch Street.

Lock-out, the act of an employer, who, by reason of trade disputes, or other cause, closes his factories or workshops against his employees.

Log, a line used for reckoning the speed at which a ship is travelling. It was first used in the 16th century. The line is divided into spaces of 50 ft. marked off by knots and measured by a half-minute sand glass, bearing the same proportion to an hour as 50 ft. bear to a mile.

Log-Book, the book in which the records of the takings of a ship's log, as well as the chief incidents of a voyage, are entered.

Long-Dated Bill, a money-market term denoting a bill of exchange for a longer than ordinary period.

Long Exchange, a term referring to the rate of exchange on bills having three months to run.

Long of Stock, an American Stock Exchange expression referring to one who holds stock in anticipation of a rise; equivalent to our "bull" operations.

Made Bill, a bill of exchange negotiated in England and payable in another country.

Maintenance, a legal term signifying the interference in a suit by someone having no direct interest in it, and constituting a punishable offence.

Making a Market is a word sometimes adopted by company promoters prior to share allotment in order to force a demand. Brokers are commissioned to buy in the market at a price slightly beyond the nominal value, a jobber is arranged with to sell them, and an artificially manipulated demand is started. Thus a favourable impression of value and demand is created, and the public may be induced to apply for shares in considerable numbers.

Making a Price, the quotation by a jobber of the price at which he is prepared to buy or to sell.

Making-up Price, the price at which stocks or shares are closed for the current settlement.

Mandamus, a writ commanding the performance of certain acts or duties.

Manifest, a document giving particulars of the various packages comprising the cargo of a ship, and the port for which she is bound.

Manifolding, a cant term applied to a fraudulent trick with half notes. A man cuts a banknote in two, sending one half to one tradesman with an order for goods, and the other half in the same way to another tradesman, impressing upon both the importance of despatching the goods immediately.

Margia, a covering deposit with a broker, accompanied by instructions as to prices that are not to be exceeded.

Maritime Lien, a claim for salvage, damages, wages, or payments made in respect of any maritime adventure and constituting a direct charge upon the vessel enforceable by arrest and sale.

Market Over, in open market, i.e., a place sanctioned by law or custom for selling and buying and open to the public.

Mate's Receipt, the receipt given by the mate of a ship when goods are brought alongside for loading.

Memorandum of Association, the document which contains particulars of the specific objects for which a company is established, and covering the whole scope of operations, beyond which it is not legal to go.

Metalling Clause, a clause in a marine insurance policy, specifying the non-liability of the underwriters for loss caused by ordinary wear and tear.

Metric System. (See *Office Compendium*.)

Mint Par of Exchange, the weight of gold or

silver in a coin of one country in comparison with that of another country's coin.

Mint Price of Bullion indicates the number of coins into which a given weight of bullion is divided.

Mixed Currency, a currency partly of coins of the precious metals and partly of convertible paper, but both must be of legal tender quality.

Mixed Policy is a marine insurance policy combining time and distance conditions—a voyage and a period.

Monometallism, the system of a single metal standard of value in a national currency, such as the gold standard obtaining in England.

Month. The term month in commercial matters means a calendar month, unless otherwise specified.

Mortgage, a legal document whereby one who borrows money conveys his right to certain property to the lender as security for the repayment of the sum advanced, together with interest at a rate specified in the deed. The borrower is called the mortgagor, the lender the mortgagee. A mortgage may be on freehold, leasehold, copyhold, or personal property. The most usual kind of mortgage is a mortgage of real estate, and it takes the form of an absolute conveyance of the property constituting the security; but, for the protection of the mortgagor the deed contains a proviso of redemption, to the effect that if principal and interest be repaid on a certain date (usually six months after the execution of the mortgage) all claim of the mortgagee on the property becomes extinguished. As a rule, however, mortgages are arranged to extend over indefinite periods, and after the expiration of the time prescribed in the proviso of redemption, the mortgagor's legal right of redemption ceases. Then, according to the strict legal construction, the mortgagee becomes absolute owner of the property; but the mortgagor has still what is called his equity of redemption, which entitles him to continue in possession of the property, and to demand the legal retransfer of it to himself on payment of the sum borrowed and interest. It is customary for mortgages to continue for a number of years (sometimes there is a precise term fixed), and so long as the interest is regularly paid by the mortgagor, the mortgagee takes no further steps. If there be failure in payment of interest, the mortgagee gives notice to the mortgagor that unless the default be made good within three or six months he will proceed to exercise the powers of sale or foreclosure given to him by the mortgage, or enter into possession of the property, but in carrying out any of these powers he can only realise to the extent of satisfying his claim for principal, interest, and expenses. Whatever surplus remains beyond this he must hand over to the mortgagor. The same process and conditions obtain when the mortgagee (even if there have been no default in the payment of interest) desires to recall the mortgage sum advanced, and gives the requisite notice. When a mortgagee fails to obtain repayment as stipulated, the most usual course is to act on his power of sale and sell the property mortgaged. To foreclose and become absolute owner, he must obtain a decree of the Court of Chancery, but such proceedings are beset by difficulties and are not frequently resorted to; nor is it often that a mortgagee takes steps to enter into possession of the mortgaged property, having to obtain leave of the Court, and being practically only in the position of a receiver, accountable for the management of the property, collection of rents, etc. A mortgage of leaseholds is by assignment or sub-lease, and of copyholds by what is called conditional surrender.

Mutual Life Insurance, a system of life insurance carried on by members of a company having no shareholders and no subscribed capital, and dividing the whole of its profits amongst its policy-holders.

Name Day, the second day of the Stock Exchange settlement. Also called the "Ticket Day."

Navy Bills, bills of exchange drawn by naval officers against pay falling due.

Negotiable Instruments and Negotiable Paper, such bills, notes, cheques, warrants, bonds, and other documents as are by common usage dealt with as equivalents of coin, and the rights in which pass to the persons to whom they are paid.

Net or Nett Weight, actual weight of goods after every allowance has been made for package, waste, etc.

Nominal Exchange, the state of the exchanges which depends upon the moneys of the countries, and not on the current demand for them at any given time.

Nominal Partner, one who permits his name to be used in the title of a business although having no actual interest in the concern, as in the case of one who has retired from it.

Nominal Price, an approximate or designated price of issue of shares, or price quoted in respect of goods and securities in which dealings are infrequent.

Notaries are generally lawyers appointed to certify signatures to documents intended for use abroad, and to put marks of protest on bills of exchange and promissory notes, foreign and inland, which have not been met.

Notice of Dishonour, the notice which the holder of a bill of exchange must give to drawer and negotiators when the bill is refused payment.

Noting a Bill, a notary's memorandum written upon the face of or attached to a returned bill, after being presented by him a second time and not paid.

Not Negotiable. When a cheque or bill has these words written across its face they do not limit the transfer of it from one to another, but, in the case of a transferor not having a good title to the document, the transferee is merely in the same position as the transferor, and cannot go back upon the original drawer for satisfaction.

Novation is the act of replacing a debtor by another who assumes the responsibility, to which there must be the assent of the original debtor and creditor as well as of the substitute.

Nudum Pactum, an agreement without consideration. Not capable of being sued upon except under seal.

Obscuration, a customs term specifying the difference between the actual and the indicated strength of spirits.

Official Assignee of the Stock Exchange, a member of the house appointed to wind up the estate of a defaulting broker.

Official Broker, one appointed to buy or sell specified securities in cases of non-delivery.

Official Receiver, a person appointed by the Board of Trade to carry out prescribed duties under the Bankruptcy Act, in connection with the winding up of bankrupts' estates, and having the powers of a trustee in bankruptcy.

Official Referee, a High Court official appointed to deal with actions concerning disputed accounts.

Omnium Stock, stock capable of being divided into proportionate parts of other stocks.

On Call, money lent, either repayable on demand or at short notice.

On Demand, a term in general use to denote bills of exchange in which these words have been written. They need no acceptance and are payable on presentation.

One Man Company, a company in which all the shares, except those necessary for constituting a company, are held by one man, or in which one man is the moving spirit.

One Man Mark't, a term denoting a case of the entire dealings in a certain class of shares being in the hands of one jobber.

Open Cheque, an uncrossed cheque payable on presentation to "bearer" or "order," as the case may be.

Open Credit, credit given by a banker to a customer without guarantee or security. A letter or credit authorising payment of money to another person without condition also comes within the term "open credit."

Open Policy, a marine insurance policy, the full amount of which is not declared until the value of the property has been ascertained.

Open Slip, a slip of paper initialed by the underwriter, having reference to the terms of an open policy, and requiring no stamp.

Option, a right granted to a person to buy or sell certain stock or shares at a specified price within a stated period or on an indicated day. (See **Put and Call**.)

Ordinary Stock or Shares, such as have no special privilege or right attaching to them, but which receive dividends representing the profits after paying interest on preference shares and debentures and providing for reserve, etc.

Original Bill, the first of a duplicate or triplicate set of foreign bills. The term also applies to a bill which has been discounted before endorsement.

Over-Capitalisation, the circumstance of a company having more capital to pay interest upon than it has power to earn, a result usually caused by too large a price having been paid for the taking over of the business, or in promotion.

Overhead Price, a price including extras.

Over-Tonnage denotes the providing of a greater tonnage of ships than is required for the freight to be shipped.

Par, a price that is equivalent to nominal value.

Par of Exchange, the equalising of exchange as between the currency of one country and that of another.

Partings, or Parting Bullion, mixtures of gold and silver, called a gold parting when gold predominates, and a silver parting when the reverse.

Partners are persons associated in the carrying on of a trade, industry, or business jointly; and may be active, as when employing themselves in the conduct of the enterprise; sleeping, when providing capital but taking no active part; or nominal, when only lending their name.

Partnership, an association of not more than twenty and not fewer than two persons for trading purposes, whose interests, relationship, and responsibilities are usually defined in a deed of partnership.

Passive Bonds and Shares, bonds on which no interest is paid but which confer some future accruing advantage on the holder.

Patent Laws. It was usual in England, up to January 1st, 1905, for the Patent Office to indiscriminately accept fees for registering and granting "protection" to "inventions." Now the Patent Office examines its records before issuing its papers. Each complete specification is subjected to a rigorous examination to discover whether the idea infringes any British patent granted within the preceding fifty years. If the result of the examination is unsatisfactory the applicant is asked to amend his specification. If he refuses, the Comptroller, after a hearing, may compel him to put in a reference to prior specifications, by way of notice to the public, the applicant having the right, however, of appeal to the law officer—the Solicitor-General. The issue of a patent does not prove its validity. As before, any person who thinks his patent anticipates that of the applicant may oppose the grant of the latter by filing a certain form and paying the requisite fee of 10s. Evidence will then be taken by the Comptroller, the final decision as to validity remaining, as before, with the law courts. The law as to British patents and designs was consolidated by an Act of 1907, which placed a check on the under-minute taking out of patents in this country by foreigners, and provided better safeguards and facilities than had previously existed. Over 30,000 applications for British patents are made annually, but less than half the number are granted as a rule.

Pawnbroking originated in Italy in the 15th century, and extended to this country some years later, the Bishop of Winchester being responsible for its introduction, though he did not charge interest. In the 18th century pawnbroking grew to be a regular business and was regulated by Acts of Parliament. A licence is required by every pawnbroker, for which he pays £7 10s. per annum, with an additional duty of £5 15s. if he deals in plate. The three balls which hang over the pawnbrokers' shops are the ancient arms of Lombardy, the Lombards being the first money-lenders in Europe. (See **Monte-de-Piété**, *General Information section*.)

Pay Day, the day on which Stock Exchange settlements are concluded. Used also to denote the particular day of each month on which a firm pays its accounts.

Payee, the person or firm to whom a bill of

exchange, promissory note, or sum of money is made payable.

Payer, one who pays a bill of exchange, promissory note, or account.

Paying-in Slip, a printed form on which particulars and details of a total amount are written when a customer pays a sum into a bank, indicating how it is made up.

Payment Supra Protest, a payment made after protest has been made denying all or part liability.

Per Capita, per head.

Permit, a customs document of authorisation to remove dutiable goods.

Personal Property or **Personalty**, everything that is possessed apart from that which is freehold.

Per Stirpes, by "stock, or stump, or root," a legal term denoting a succession of next-of-kin by simple right of representation, as grandchildren taking their parents' share under their grandfather's will.

Petitioning Creditor, one who files a petition in bankruptcy against a debtor.

Placing Shares, the act of a broker or brokers in getting people to take up shares, usually referring to such as are placed in order to make up a sufficient number to secure quotation on the Stock Exchange.

Policy Holder, the possessor of a policy, whether the insured, or one to whom the policy has been assigned.

Policy Proof of Interest, an expression signifying that the underwriters will recognise the holder's interest in a policy on producing it, without calling for additional proof.

Pool, the combining of several persons in one large operation in shares, on condition of equal sharing in profits or losses according to the amounts of their respective subscriptions.

Post Note, a bank note made payable to order. Such a note must be endorsed by the payee.

Post Oblit Bond is a bond given for a loan, undertaking to repay the lender the sum borrowed with interest, after the decease of another person from whom he expects to receive money.

Pratique, a licence for a ship to trade in specified ports, provided the port she sails from is free from infectious disease.

Preference Bonds are such as are issued at a fixed rate of interest, and payable before dividends are declared on ordinary shares.

Preference Shares and **Preference Stock** are shares or stock entitled to their fixed dividend before any division of profits can be made amongst the holders of ordinary shares or stock. Preferential rights may be cumulative or non-cumulative.

Preferential Payments in Bankruptcy are such as have to be made before the claims of ordinary creditors are considered, and include rates and taxes which may have become payable within two months preceding the date of the receiving order; wages or salaries of clerks or servants for services during the preceding four months, and not exceeding in any one case £50; wages of labourers or work for services during the preceding two months, and not exceeding in any one case £25.

Prejudice, Without. When statements are made or letters written with the words "without prejudice" affixed, they cannot be afterwards used as evidence should litigation follow.

Premium has several meanings: (1) a prescribed periodical (usually annual) payment on a policy of insurance; (2) the advance in price of stock or shares above par value; (3) a bounty; (4) a payment in respect of a loan, in addition to or in place of interest.

Pre-Preference Securities are issues that take preference even of preference ones, but are seldom resorted to.

Present Value, a term used in discounting, and referring to a simple deduction of interest from the face value of a bill; the determination of the present value of a deferred payment with compound interest; or the calculation of the present value of a series of payments due at regular intervals.

Prices Current, a list of goods and merchandise

with prices and statements, duties, drawbacks, etc., if any.

Pricking Note, formerly a Custom House authority requesting the chief officer of a ship to receive specified bonded goods for exportation. The term is now obsolete. (See **Shipping Bill and Note**.)

Primage, a percentage added to the freight and paid to the shipowner to cover commission for chugging, etc.

Primage and Average Accustomed, an expression often introduced into a bill of lading and referring to charges for covering cost of wharfage, lights, pilotage, &c. There is no separate charge now for average, that being included in primage.

Prime Entry, the first entry of the estimated value of a ship's cargo, on which duty has to be levied, before the vessel can begin discharging.

Private Arrangement, a deed whereby a debtor and his creditors enter into an agreement for the payment and acceptance of a composition in satisfaction of all claims.

Private Company, a small limited company privately formed by members who subscribe the whole of the capital among themselves.

Produce, one who manufactures goods, or one who grows and cultivates the produce of the ground.

Production, a term used to denote a thing produced—that is, made, written, composed, or manufactured; or, in its ordinary commercial significance, the bringing forward and offering of an article for sale.

Productive Labour is divided into three somewhat widely generalised classes: *Productive*, such as minister to human gratification and enjoyment, but can not be stored—*as*, for instance, the services of actors, singers, &c.; *Protective*, such as the labour of soldiers, policemen, judges, &c.; and *accumulative*, those services which produce material objects capable of being stored or exchanged, as those of the mechanic, the factory worker, and so on.

Profit, the surplus remaining after all expenses attending production and sale have been deducted.

Promissory Note, an unconditional written promise to pay a specified sum on a specified date, to, or to the order of, a specified person.

Promoter, one who employs himself in the preliminary work necessary to the flotation of a limited company, and whose remuneration must be stated in the prospectus.

Proof of Debt in Bankruptcy, a creditor's affidavit or declaration, setting forth particulars of debt owing to him by a bankrupt.

Property is of two classes, corporeal, as land, buildings, &c., and incorporeal, as the rights in things not represented by material objects.

Prohibitions and Restrictions, a term applying to articles which are either prohibited altogether from being exported or imported, or are placed under special conditions.

Proprietary Company, a parent company holding lands or mining rights, parts of which it sells or leases to others.

Prospectus, a document containing a statement of the property, business, undertaking, enterprise, or project for the development or working of which an appeal is made to the public to subscribe for shares in the company taking the property over. The provisions with regard to false statement or concealment of facts are exceedingly strict, and persons who have been induced by misstatements in a prospectus to take shares can proceed against its issuers for damages.

Protest, a notification by a notary public of an unaccepted or unpaid foreign bill of exchange, which protest must be effected at the place of dishonour, and contain a copy of the bill, a statement of the parties to it, and other particulars.

Proxy, one who acts for another, or the written authorisation for such action. A proxy requires rd. stamp, but for proxies in bankruptcy or winding-up proceedings there is stamp exemption.

Public Company, a limited company whose capital consists of shares publicly subscribed, such shares being saleable by any shareholder without the consent of the other shareholders.

Put, or "put option," is the right to sell certain stock at a price named on a specified day, in consideration of a premium paid.

Put and Call, equivalent to double option.

Put of More, a "put option," with the additional privilege of selling double the quantity specified.

Pyx, **Trial of the**, is a trial by a jury of experts chosen from the freemen of the Goldsmiths' Company of the City of London, of the gold and silver coins manufactured at the Royal Mint, and in recent years at certain Colonial Mints, during the preceding twelve months. This annual ceremony takes place in accordance with the provisions of the Coinage Act of 1870. The standard pieces of gold and silver used formerly to be kept in the ancient Chapel or Chamber of the Pyx at Westminster Abbey, under the joint charge of the Lords of the Treasury and the Comptroller-General. (See also *Mint*.)

Quarantine is a term used to denote the period for which a vessel, on which there is infectious disease, is detained in isolation until medically certified free from taint. Originally this period was forty days; hence the term, but now the detention and prohibition of intercourse with the shore only lasts until a clean bill of health can be given.

Quarter Days in England are Lady Day (25th March), Midsummer Day (24th June), Michaelmas Day (Sept. 29), and Christmas Day (Dec. 25). In Scotland the legal terms are Whitsun (May 25), Martinmas (Nov. 11), and the conventional terms Candlemas (Feb. 2), and Lammas (Aug. 1) make up the quarters.

Quit-Rent, rent paid in respect of copyhold property to a lord of manor in lieu of services.

Quintal, a weight that varies in different countries. In England and the United States it is 100 lbs.; in France, 100 kilos, equal to about 220½ lbs. avoirdupois.

Quorum, a term indicating the number of members of any body or company necessary to be present at any meeting or commission before business can be transacted. The members constitute a quorum in the House of Commons.

Rack Rent, rent of the full yearly value of the property held. A term generally used to denote excessive rent.

Racking, a term used in the wine and spirit trade when liquors or wine are transferred from certain casks to other casks, or when drawn off from the lees.

Railway Advice, a document sent by a railway company to a consignee of goods intimating that goods are awaiting his orders at a specified station, and that demurrage will be chargeable after a date named.

Rateable Value, the value of property as the same is assessed in the rate books of the local authorities, representing the ordinary rent value less the outgoings in connection with the property.

Raw Materials are products before they have come into process of manufacture, such as wool, cotton, hemp, etc.

Real Estate or Realty, includes all freehold property. Leaseholds, however long the term, are personal estate.

Real Securities, deeds of mortgage of real estate.

Realisation is a conversion into actual cash of what was previously contingent or doubtful, a process that may result in gain or loss on original cost according to the state of the market.

Reasonable Hours, a term often used in commercial documents in regard to applications, presentations, etc., and mainly to be decided by commercial custom. Thus, from 9 a.m. to 6 p.m. would be reasonable hours in any ordinary business.

Receipt is a written acknowledgment of money paid, and since 1893 has in this country been liable to stamp duty, at first according to the amount involved, but since 1894 a uniform stamp of one penny for any sum of £2 or more has been sufficient. A special receipt stamp was necessary before June 1st, 1881, but since that date ordinary penny postage stamps have been used.

Receiver, one appointed to control an estate or property pending dispute or litigation.

Receiving Notes, documents signed by shippers requesting the chief officer of a ship to receive on board specified goods.

Receiving Order, the order of a court of bankruptcy, on petition presented by a debtor or one of his creditors, placing the debtor's estate in the hands of the official receiver, and barring further legal proceedings against the debtor by creditors. Whether the debtor be declared bankrupt or not depends upon the decision of the creditors after the debtor's public examination.

Recognizance, an acknowledgment of indebtedness to the Crown, should a certain specified act not be duly performed; for example, a recognizance in respect of a prisoner liberated on bail, whose failure to appear on the day appointed for trial, would render the recognizance realisable.

Redemption of Mortgage, paying off principal sum, and interest due on a mortgage, and thereby redeeming the charge.

Re-draft, a new bill of exchange in place of one that has been protested, with costs added to the original amount.

Re-exchange, loss incurred on a dishonoured foreign bill.

Re-exportation, the exportation of imported goods.

Reducing into Possession, the conversion of a thing in which one has the right of action into actual possession, as when the holder of a bill of sale enforces his security.

Reference, a person or firm to whom inquiries may be addressed regarding the character, ability, or position of the one giving the reference.

Registered Bonds are such as for security against robbery or loss are registered in the holders' names in the books of the company or State issuing the bonds.

Registered Stock is stock registered in the same manner as mentioned in regard to Registered Bonds above. Holders of such are given a certificate of title.

Re-insure is to take out an additional insurance on the same risk, and occurs when an insurer considers that he has incurred too great a hazard and re-insures with others, so as, in case of loss, the liability will be more widely distributed. Re-insuring, however, does not lighten the insurer's responsibility for the whole amount of the original insurance.

Remedy, the technical term for the extreme limit of allowance the Mint will allow from the fixed coinage standard.

Renewal of a Bill is frequently resorted to when an acceptor finds himself unable to met it when it falls due. It simply amounts to an extension of time, but cannot be effected without the consent of all the parties to the original bill.

Rentes, foreign Government Funds—chiefly those of France, Austria, and Italy—on which annuities are paid, as with English Consols.

Replevin, the name of an action brought by a tenant for recovery of goods unlawfully distrained upon.

Reputed Ownership is a term in use regarding goods and property in the possession of a bankrupt, and applies to everything under his control at the time of his bankruptcy. All such property is presumed to belong to the bankrupt and to be available for realisation and distribution, unless the contrary is proved.

Request Note, a note filled up and signed by an importer when requiring the removal of dutiable goods from one warehouse to another, or (in the case of perishable goods) from shipboard before clearance.

Reserve, a fund set apart by a company, firm, or institution, over and above its capital, to provide for contingencies.

Reserve Capital, such portion of a limited company's unpaid capital as can only be called up for winding-up purposes.

Reserve Price, the lowest price at auction or otherwise at which specified goods will be sold.

Respondentia, a legal term applying to maritime contracts, mortgages ships and their cargoes for money advanced; differing from a bottomry bond in the extent of the pledge.

Resolution, any proposal made at a meeting and put to the vote. An ordinary resolution of a limited

company is decided by a bare majority; a special or extraordinary resolution requires a majority of three-fourths to carry it. The "special" resolution must be subsequently confirmed by a mere majority, but no confirmation is necessary for an "extraordinary" resolution.

Rest, a Bank of England term applied to its weekly return, and signifying the surplus of assets over liabilities (including capital).

Restraint of Trade, a term applying to an arrangement entered into when a business is sold, prohibiting the seller from carrying on a like business within a specified radius or during a given time. Anything in the nature of unreasonable restraint cannot be upheld.

Restrictive Endorsement is one which destroys the negotiability of a bill of exchange.

Refainer, the engagement, by request and payment of retaining fee, of the services of a counsel to represent one of the parties to an action, inquiry, trial, hearing, or arbitration. Another meaning of the word refers to the right of an executor to retain what may be owing to him personally out of the testator's estate from moneys coming into his hands as executor.

Retenue, a French term for the charge made to importers of gold and silver for the conversion of bullion into coin at certain mints. (See **Seigniorage**.)

Retiring a Bill is to withdraw it from circulation after by buying it up and retaining it until maturity or at once cancelling it, or by the acceptor meeting it in the usual way when due. In the latter case it is discharged.

Revenue, in its ordinary application refers to income of any kind; more strictly, however, it is a word denoting the income yielded to a State from taxes and duties.

Revenue Account, the account of a firm or company showing the result of its operations and what profit or loss it has made. It is apart from the capital account.

Reversion is a right to property or benefit, the enjoyment of which does not come into operation until the happening of a certain event or the expiration of a certain period.

Reversionary Interest, a term generally applied to a deferred interest in money or personal property.

Rider, any separate addition to a document, or addition to a resolution or verdict, fastened to the original.

Rigging the Market is a Stock Exchange practice sometimes resorted to whereby persons by secret purchases of a particular class of stocks or shares force an artificial public demand, and consequent rise of price. Then they sell.

Right of Action is the right, obtained by argument or purchase, of claiming or suing for a debt or obligation due to another.

Ring, a combination formed by a group of speculators to obtain control of the operations in a certain commodity, and by creating scarcity to run up prices for their own profitable realisation. (See **Corner**.)

Royalty has several meanings: (1) percentages or dues payable to landowners for mining rights; (2) sums paid for the use of a patent; (3), percentages paid to an author by a publisher on the sales of a book.

Rolling Stock, everything used on railways or tramways for the conveyance of passengers or the transport of goods, and including locomotives, electric motor cars, carriages, wagons, etc.

Rummaging a Ship is the search made by Customs officers for concealed dutiable or prohibited goods.

Runner, one who touts for sharebroking business and is remunerated by a share of the profits on what he introduces, while also liable to bear a share of any losses made.

Running Days, consecutive days, including Sundays and holidays, and used in regard to a ship's running.

Rus with the Land, any condition of tenancy or leaseholding that is special to a property let or

leased and for which continuous fulfilment has been provided.

Sagging Market is one in which prices show a marked and continuous falling tendency.

Sale for the Coming Out is an early sale of shares in a company prior to the issue of share certificates.

Sale or Return, a selling of goods to a retailer on condition that if he fails to re-sell them within a given time the seller will take them back and refund the money paid for them or make an equivalent allowance.

Sale Warrant, a document given with a weight note, in the case of goods sold on payment of deposit, conditionally on an early discharge of the balance.

Salvage, compensation given in respect of property saved from the perils of the sea, when the ship containing it has had to abandon it, or it has been lost. Salvage compensation varies from one-tenth to one-half the value of the rescued property.

Salvage Loss, a term used in respect of a partial marine insurance loss, being the value of the goods recovered deducted from the full amount of insurance.

Sampling Orders are orders addressed to the superintendent of a dock or other warehouse, authorising the giving of specified samples to the person named.

Sans Recours, "without recourse," a term which when written on a bill of exchange by an endorser frees him from liability on the document.

Schedule, a list, summary, index, or inventory. It may be either supplementary or explanatory.

Scrp, a certificate of shares in a Government loan, company, or corporation, a contraction of "subscription."

Seorvener, one who lends or invests money for clients at interest, and is remunerated by commission or procuration fees.

Scrutineer, a person appointed to count the votes at a general meeting of the members of a company.

Scrutiny, an examination of voting papers.

Searchers are Customs officers entrusted with the duty of searching and examining vessels on arrival or departure for goods liable to duties.

Search Warrant, a document issued by a magistrate authorising a search in any place for stolen or concealed property.

Seaworthy, the condition of a ship when it is in every respect fitted for undertaking a voyage. There is an implied warranty of seaworthiness in a marine insurance policy, and should the vessel turn out to have been inefficient at starting, the underwriters have their remedy against the insured.

Second Class Paper, bills, notes, and other securities for the satisfaction of which persons or firms of only moderate standing are responsible.

Secured Creditor, a creditor holding security the realisation of which would satisfy his claim; what it realises beyond that must be handed over to the debtor's estate. In such a case the creditor is fully secured. In case of a partially secured creditor, he may realise on the security as far as it will go, and prove on the estate for the balance.

Securities are documents entitling the holder to specified realisable rights in land, money, stocks, shares, bonds, mortgages, etc., in the event of loans, payments, or advances for which they were given remaining undischarged.

Seigniorage, a Mint charge for converting bullion into coin. The seigniorage on gold is 14d. per Troy ounce, while on silver there is no charge for coining.

Seisin, actual possession of real estate.

Seizure Notes are notes made out by a Customs officer on discovering and taking possession of goods fraudulently obtained or bearing fraudulent trademarks, and left with the goods after they have been placed in a Customs warehouse.

Sellers Over, a market condition when sellers are in excess of buyers, or when there are no buyers at all.

Selling Out, a Stock Exchange term applying to the case of a buyer of stock for the account failing to pay for it, when the stock is officially sold and the transaction closed, any loss that may be incurred being charged against the defaulter.

Sequestration is a legal process putting a sheriff or other officer of court in possession of property or goods until a dispute or claim in respect thereof has been disposed of.

Sequesteror, the person appointed to take possession under a sequestration order.

Set-Off, the placing of a debt due against a debt owing, wholly or partially.

Settlement may mean: (1) the discharge of a debt or claim; (2) the settling of a sum of money on a woman on her marriage as a provision for herself and children; and (3) the Stock Exchange fortnightly settling period, viz. the last three days of the month, as to general stocks and shares, and in the mining market four days.

Settling Day, the last day of the Stock Exchange account.

Sharebrokers are persons engaged in the business of buying and selling shares and stocks for clients.

Share Certificate, a document issued by a public company to a shareholder, certifying the number of the shares held, and the sum paid up on them.

Share Warrant, a document certifying that the bearer owns the shares specified and that they are fully paid up. It is a negotiable instrument, with coupons attached payable at the dates named to whomsoever may present them. When shares take this form the shareholder's name does not appear on the list of shareholders.

Ship Brokers are persons engaged in promoting business between shipowners and traders.

Ship Letter, a letter despatched by a private vessel and not by the usual postal channels.

Shipping Articles, the contract between a shipmaster and his seamen setting forth the terms and conditions of service.

Shipping Bills, Customs or traders' documents containing particulars of goods placed on shipboard.

Shipping Cards, cards issued by shipbrokers giving dates of sailings, approximate dates of arrivals, and other information of use to shippers.

Shipping Note, delivery or receipt note concerning goods sent for loading.

Shipping Weight, the declared weight of goods put on shipboard.

Ship's Certificate of Registry. This is issued by the registrar after the completion of the building of a ship, and sets forth the name, build, tonnage and other particulars.

Ship's Clearance Inwards, the Customs certificate that all dues and demands in respect of a home-arriving ship have been satisfied.

Ship's Clearance Outwards, the Customs certificate that all dues and demands in respect of an outgoing vessel have been satisfied.

Ship's Manifest, is a ship's paper, and contains full details of the vessel's cargo and the ports for which she is bound.

Ship's Papers, such as must go with the ship, comprise the Certificate of Registry, the Contract with the seamen, Charter Party or Bills of Lading, Manifest, Official Log, and Bill of Health.

Ship's Passport, a State document, given in time of war to the master of a neutral ship, containing all particulars necessary to show the vessel's nationality, ownership, equipment, cargo, etc.

Ship's Protest, a declaration, made before a notary, setting forth particulars of loss or damage to ship or cargo, a document necessary for production to underwriters before adjustment of claim.

Ship's Report, a form which every master of a ship is required to fill up within twenty-four hours of arriving in port, setting forth all particulars as to vessel, crew, cargo, etc.

Ship's Store Bond, a document given by a shipowner or captain in respect of dutiable articles to be used as stores during a voyage.

Ship's Stores, articles necessary for the provisioning of a ship; as a Customs term, however, it refers only to articles which would be chargeable with duty if consumed on land.

Share Bill are bills of exchange having less than ten days to run.

Short Exchange, rates quoted for bills payable on sight or within a few days after.

Short Loans, advances for short specified periods at a fixed rate of interest.

Short of Stock, a phrase, originating in America, to denote a selling of what is not possessed, and answering to "bearing" operations.

Short Shipment, a term applied to goods that, through accident or want of space, are unable to be taken on board.

Shut for Dividend refers to the period when the transfer books of the public companies are closed for the making out of the dividend warrants. No transfer can be registered during this period.

Sight Bills are such as are payable at sight, without allowance of days of grace.

Sighting a Bill, a bill is sighted when presented to the person on whom it is drawn.

Sinking Fund, was established by Sir Robert Walpole in 1716 with the object of redeeming the National Debt. A further Sinking Fund was introduced by Pitt in 1786 that ultimately proved to be founded on a fallacious basis. In 1868 the Sinking Fund was restricted to one-fourth of the actual surplus revenue, and a new Sinking Fund was formed in 1875, by which a permanent annual charge to be sanctioned by Parliament from time to time was established, the yearly charge from that date being fixed at 28 millions sterling.

Shipping, a Customs term used in taring, and referring to the temporary transfer of articles from one package to another.

Slander of Title or of Goods, anything uttered in denial of ownership or depreciation of goods, whereby a man suffers loss of sales or custom.

Siding Scale, a scale of wages regulated by appreciation or depreciation in the market value of the products of labour.

Slinging, the act of putting chains round goods lying on the side of a ship for convenience of hoisting. The shipper bears the charge for this.

Slip, a marine insurance term referring to a note of particulars required by an underwriter before undertaking to insure, and which he initials if accepting.

Sola, signifying "this only," is a term applied to a document of which only the original exists.

Solvency, the ability to discharge all debts and obligations in full.

Specific, metallic money, coin, in contradistinction to instruments of credit, such as bills and notes.

Special Commerce, a term including imports for home consumption and exports which mainly represent the products of the countries from which they are exported.

Special Damage is damage sustained by wrongful act and for which damages beyond general damages may be claimed.

Special Endorsement on a bill of exchange is an endorsement specifying the name of the person to whom the indorser transfers the document.

Special Settlement is the day fixed for first settlement upon which stock is first admitted to quotation on the Stock Exchange.

Specie Point, the point above or below the Mint par of exchange it is found more profitable to pay in specie than bills.

Specification, a detailed list of work to be done or goods to be supplied in the carrying out of an order or contract.

Specific Performance, the express carrying out of the terms specified in a contract. Where damages supply an adequate remedy, however, the court seldom enforces specific performance.

Spits, instruments of wood, iron, or steel, used by Customs officers in examining goods for dutiable articles.

Spot Goods are such as are ready for immediate delivery.

Squeezing the Bears, a phrase denoting the condition to which "bears" are reduced when buyers to whom they have contracted for delivery are themselves the holders of the available stock, and by this means compel the "bears" to purchase from them at an advanced price.

Stag, one who buys shares in a new company with the view of operating for premium only, selling as soon as premium point is reached.

Stale Cheque, a cheque that is not presented for payment within a reasonable period. Bankers make a rule of not cashing cheques six months or more old.

Standard Gold is composed of twenty-two parts of pure gold and two parts of copper alloy.

Standard Silver consists of thirty-seven parts of pure silver and three parts of copper alloy.

Standard Money is coin whose value in exchange depends upon the intrinsic value of the metal it contains.

Standarding is an arithmetical calculation for ascertaining the value of bullion, that is converting the gross weight of gold or silver that is not of the standard into its equivalent in weight of standard metal.

Staple, meaning that which is appointed, was an old English term used to designate the commodities traded in by privileged merchants and on which customs were levied. The chief staples were wool, skins, leather, tin, lead, and money. Acts were passed regulating and varying the staple towns from time to time.

State Notes are the notes of a State or Government, undertaking to pay bearer on demand the amount specified in specie.

Statute Barred, a commercial term denoting a debt has passed beyond the limit within which it can be legally recovered.

Statutory Meeting of shareholders in a company is a general meeting which it is compulsory to hold within not less than a month and not more than three months from the time of starting business.

Stay of Execution, an order of court suspending execution on a judgment obtained, until an appeal which has been moved for has been heard.

Sterling Bonds are such as are payable in British currency only.

Stiffening Order, a Customs House permit for a ship before coming to anchor to take ballast or heavy cargo on board for steady purposes.

Stock represents the consolidation of shares and other securities into a money basis of value, and includes the national debt of a country, and fully paid-up shares in a company, and, unlike shares, is divisible into fractional parts.

Stock Exchange, a building in which the operations of buying and selling stocks and shares are carried on. The London Stock Exchange is controlled by a committee of thirty members. There are two classes of members—jobbers and brokers; jobbers dealing in particular groups of stocks, and brokers who operate generally between the public and the jobbers. The annual subscription is forty guineas; and to become a member a man must have served as clerk to a member for two or four years. He must be a member of the club after two years he pays 50 guineas, if after four years 50 guineas.

Stock Receipt, a receipt of registered stock given to the purchaser by the seller on payment of the consideration. On production of this receipt the purchaser's name is registered as owner.

Stopping a Cheque or Note, an act resorted to when a cheque or note has been lost or stolen. The bank is notified of the loss or theft, and in the case of a cheque the banker may refuse to cash it; but as regards a note the banker can only explain matters to anyone presenting it for cashing; he cannot refuse payment if insisted upon, although the presenter may perhaps be arrested immediately afterwards.

Stop Order is an American Stock Exchange term referring to an order to a broker to sell stocks or shares on reaching a certain figure, the price to be made by a third party, and not the broker himself. Should a purchaser not be forthcoming, the broker is at liberty to sell at the next lower price.

Stoppage in Transitu, a seller's right to stop goods on the way to delivery on discovering after despatch that the purchaser is not solvent.

Stores, a maritime term referring to provisions, etc., for the victualling of a ship. Also used to denote any large retail establishment, or goods in bulk generally.

Stowage, payments for stowing a vessel.

Strike is a combined withdrawal from work of a body of workers, for the purpose of obtaining higher wages, or securing some other demand.

Subpoena, "under a penalty," a writ of court commanding the attendance of a witness at a specified time and place. It is called a *subpoena ad testificandum* when requiring verbal testimony only, and a *subpoena duces tecum* when requiring the production of documents.

Subsidy, money contributed by a State, Government, institution, or person, in behalf of any special object.

Superfence Wharf, a licensed wharf upon which dutiable goods may be landed and stored until the duty is paid.

Sum Payable, the amount payable on a cheque, bill, promissory note, or draft, and written out in full in the body of the document. If by error the sum written in figures in another part does not tally with the amount as written out in full, the latter will be deemed correct.

Surrender Value, the value of a life insurance policy at any given time when the person insured because of inability to continue paying premiums, or for other cause, desires a lump sum to be paid to him in consideration of what he has already paid and of his giving up the policy.

Suspense Account, an account of transactions which because of death, lack of information, or other cause, it is impossible to enter in the books in the regular way, and they have to be held in suspense.

Suspension of Payment is when trader, firm, or companies, unable to cope with their liabilities, decide to cease paying further debts, and announce the fact to their creditors. After this step the whole of the assets become available for the whole of the creditors and the estate is wound up.

Take In, to obtain backwardation.

Taking In Shares is when a person having bought more shares than he can take up on the setting day, commences to receive him a portion of them.

Taking Up a Bill is discharging it when it falls due. The acceptor has the first responsibility, and if failing him, it is taken up by an indorser, the latter can sue the other parties previously liable on the bill.

Tale Quale, a grain trade term, denoting that goods sold are equal to sample but that any loss by damage during transportation must be the concern of the buyer.

Talon is the last portion of a bearer-land coupon sheet, containing the intimation that on presentation a fresh sheet of coupons will be exchanged for it.

Tape Prices are the latest prices as recorded on the "tapes," of the telegraph instruments at various places, as supplied by the authority of the Stock Exchange.

Tare is the deduction made in respect of boxes, cases, or other things used in packing goods, leaving only the actual weight of the goods to be paid for.

Tariff, a list of duties charged on specified articles. The term is also applied to any list of charges.

Telegraph Restante, a direction on a telegram intimating that it has to remain at the office where received until called for.

Telegraphic Transfer are messages authorising the transfer of amounts specified from one person to another by process of debit and credit entries by bankers, and much resorted to in transactions between different countries. A trader can in this way pay a sum into a bank in London and have its equivalent paid by the bank's agent in almost any city of the world the same day.

Telegraphing Money Orders, a method of securing payment of sums of money to a person named on the order, at any post office, telegraph office other than the issuing one. No telegraph money order can be issued for a greater amount than £40.

Tenant's Fixtures are such as the tenant has himself put up, and are removable by him at the end of his tenancy, unless they are of such a nature that they cannot be detached without injury to the landlord's property.

Tender is an offer to supply certain things, perform certain acts, or pay a specified sum, but is not binding until accepted.

Tenement, a house occupied or capable of being occupied by a tenant.

Terminal Charges, railway charges for loading, unloading, and otherwise handling goods entrusted to them for transportation.

Third Class Paper bills and other negotiable securities, the responsibility for payment of which belongs to persons or firms of inferior standing.

Ticket, a document giving particulars of shares sold and given to a purchaser by his broker.

Time Bargain, an agreement to buy or sell at a future date at a price fixed on entering into the agreement.

Time Policy, a marine insurance in respect of goods in transit, and limited to a specified period.

Tolls are dock and canal charges for conveyance of goods, and are charged against the owners of the goods, not the ships.

Tonnage as registered is based, not on the carrying capacity of a ship, but upon its cubical capacity, one ton being reckoned for every 100 cubic feet.

Tonnage Duty, port charges, estimated on a ship's registered tonnage, payable on entering or leaving port.

Trade Bill, a bill of exchange in respect of which value in goods has been actually received by the drawee or acceptor.

Trade Fixtures, like tenant's fixtures, are removable by a tenant at the expiration of his tenancy provided no damage be done to the landlord's property.

Trade Mark is a distinguishing design adopted by a producer of goods to indicate his special manufactures. All trade marks are required to be registered, and the forging or counterfeiting of a trade mark is a misdemeanour, punishable by fine or imprisonment.

Trade Unions, a term applied to organisations of workmen formed for mutual protection and assistance, and for the purpose of improving the conditions of their employment generally. Combinations among various classes of workmen have been formed from time to time since the Middle Ages, and trade unions may be regarded as the lineal descendants of the old craft guilds which were suppressed in the time of Henry VIII. The growth of trades unionism was a feature of the latter half of the 19th century. After years of repression a Royal Commission on Trade Unions was appointed in 1869, and their report was followed by the passing of the Trade Union Act of 1871, which, as amended in 1876, now governs the legal position of all such combinations. Since 1866, a congress of delegates from trade unions has met annually for the purpose of discussing labour questions. There are over 2,100 Trade Unions in the United Kingdom with a total membership of about 2,000,000, over three-fourths of which belong to the building, mining, and quarrying, metal, engineering, shipbuilding, and textile trades. Usually a weekly contribution is fixed by the rules, but the income of a trade union varies according to the needs of the organisation, weekly levies being made for special purposes.

Transfer, any document whereby one person transfers property, securities, or rights to another. On the Stock Exchange a transfer of shares or stock is prepared by the seller's broker, signed by the seller, and handed over on payment of the consideration.

Transfer Days are those on which the Bank of England enters transfers free of charge of Government Stock.

Transit, a Customs document permitting a specified vessel or goods to pass or proceed, and serving for outward clearance. It is made out in duplicate.

Treasure Trove, a legal term applying to money, plate, or bullion found hidden in the earth, or elsewhere, and for which there is no owner. The treasure legally belongs to the Crown, but it is the practice to reward the finder with the full value of the property on its being delivered up.

Treasury Bills are negotiable Government acknowledgments of loans, and may be for three, six, or twelve months.

Treat, and **allowance** come common, for waste, carriage, &c., but no longer a custom of trade.

Trusts, a term applied, especially in America, to an arrangement whereby several companies are placed

under one control, mainly with a view to regulate the production and to beat down competition.

Trust Deed, a deed assigning or conveying property, debts, or securities to a trustee or trustees for the purposes set forth in such deed.

Turn of the Market, an expression referring to the difference between selling and buying prices of stocks or shares. For example, if a jobber names two prices, one is the price he will buy at, the other his selling price, and the difference between the two is termed the "turn of the market."

Uberimma Fidel, an expression of mutual good faith by contracting parties.

Ullage, waste or leakage, in liquid contents of bottles, casks, &c.

Under Protest, a commercial term signifying a payment of money accompanied by a declaration that the demand is illegal or in excess of what is justly due, and implying the need of a future rectification.

Underwriter, one who issues shares against loss (See *Lloyd's* and *Marine Insurance*). Also one who, on a limited company's prospectus being issued, undertakes, if the public do not subscribe to the amount required, himself to take up shares sufficient to cover the deficiency, on a specified commission basis.

Unclaimed Dividends are dividends which have not been claimed. In the case of Government Stock, after ten years they are transferred, along with the Stock itself, to the National Debt Commissioners.

Unfunded Debt or Floating Debt consists of Government short loans, payable at fixed dates.

Unified Stock is stock which from being of different interest-bearing rates is amalgamated into one of a uniform rate. The Consolidate Annuities are an example.

Unilateral Contract is a contract that is binding only on one party to it.

Unseaworthy, the condition of a ship when from any cause, including inadequacy of crew or captain, it is unsafe to load it or send it on a voyage.

Upset Price, the price that must be reached at auction to effect a sale. If there is no bid up to that amount the property is withdrawn.

Usury, a term originally used to denote any interest or premium paid for the use of money, but afterwards only employed to express an excessive rate of interest. Many statutes have been passed in order to restrain the practice, and although some of the old evils are continued by private arrangement, the law, as a rule, can afford protection against extortion. The Money-Lenders Act of 1900 compels money-lenders to be registered, and gives a judge the power of reducing any rate of interest he may deem exorbitant.

Vendors' Shares are shares allotted to the vendor or vendors of a business on the same being converted into a limited company.

Venture, a term used when goods are sent out to consignee on a general hazard of sale, for what can be got for them.

Warrant, (1) a magistrate's order for the arrest of a person or seizure of goods; (2) a receipt for goods deposited in a warehouse, and a negotiable document; (3) a document entitling the holder to certain money or property. (See *Dock Warrant*, *Share Warrant*.)

Warrant of Attorney, a document given by a client to his attorney authorising him to appear for him in specified legal proceedings and acts as directed, suffering judgment if necessary.

Warranty, a guarantee that goods sold are of the quality stated, and giving the buyer the right of action for damages should the goods turn out inferior.

Watering Stock, a term denoting the issue of extra shares of nominal capital, without providing for interest being paid thereon, the object being to keep down the apparent rate of interest.

Way Bill, a list of passengers or goods carried by a public conveyance.

Wharf Note, a dock company's certificate of weight and other particulars of goods imported.

Winding Up is the closing up of a company's concerns, which may be by reason of insolvency, or otherwise. (See *Liquidation*.)

Pears' Dictionary of Photography

Giving Particulars of Terms, Formulæ, and Processes employed in Photography. With numerous Practical Hints on Camera Work and its Applications.

By F. J. MORTIMER, F.R.P.S.

Editor of "The Amateur Photographer and Photographic News," and "The Dictionary of Photography."

Accelerator. The constituent of a developer that is used to hasten the process of development. Thus in a pyro-soda developer the carbonate of soda is the accelerator. An increase of accelerator in a developer has the effect of quickening the action and at the same time tends to soften the character of the developed image. (See **Developers and Development**.)

Acetic Acid. A strong-smelling corrosive acid. Should be kept in stoppered bottle. "Glacial" Acetic Acid is the strength usually employed in photography. This contains 99 per cent. of acid and 1 per cent. of water. It crystallises at about 34° F. The commercial "strong" acetic acid is one-third of the strength of the glacial acid. It is a solvent of pyroxyline.

Acetone is a volatile liquid with a pleasant smell and can be used as a substitute for alkali in various developing formulae. The following pyro-acetone developer is recommended.

Pyro	90 grains.
Water	10 ozs.
Sulphite of soda	14 ozs.
Acetone	2 lbs.

Acetone dissolves pyroxyline and is thus of special utility for repairing articles made of celluloid such as developing dishes, etc. (See **Development**.)

Acetylene is used in photography as an illuminant for enlarging and projection lanterns. Special generators and lantern jets with two or more burners and reflector are sold by photographic dealers for the purpose. (See **Lanterns**.)

Achromatic lenses that have been corrected for chromatic aberration is termed achromatic. An achromatic lens brings the rays of light of all colours of the spectrum to the same focal plane. This is a great advantage for orthochromatic and colour work. With a lens uncorrected for chromatic aberration a blurred picture would be produced owing to the superposed images of different colours not coming to the same focus. A more completely corrected lens (for colour) is termed, apochromatic. (See **Chromatic Aberration**.)

Acid-Fixing Bath. The use of an acid-fixing bath is recommended by many plate and paper makers. The bath keeps clear longer and generally tends to give brighter and cleaner results than when plain hyposulphite of soda is used. The acid-fixing bath must not be used for printing-out-papers.

A convenient formula is:—

Hypo	4 ozs.
Metabisulphite of potash	1 oz.
Water	20 ozs.

A cheaper form of acid fixing bath which works well is:—

Hypo	1 lb.
Sodium bisulphite lye	14 ozs.
Water	20 ozs.

(See **Fixing**.)

Actinometer. An instrument for measuring the actinic value or strength of light. (See **Exposure and Exposure-Meter**.)

Adapter. A contrivance consisting of supplementary flanges or rings for fitting a smaller lens to a camera-front in place of a larger one. An adapter may be extemporised for occasional use out of thick cardboard, or strips of paper may be bound round the thread of the smaller lens until it can be firmly screwed home into the ring of the larger lens which is attached to the camera front.

Adon is the name of a special form of telephoto lens made by Messrs. Dallmeyer.

Adurol. A developer for plates and bromide and gaslight papers. The following two-solution formula is a good one:—

a. Adurol	85 grains.
Sulphite of soda	14 ozs.
Water	10 ozs.
b. Carbonate of potash	14 ozs.
Water	10 ozs.

For normal exposures use:—

a. 1 part.	b. 1 part.	Water. 1 part.
------------	------------	----------------

The developed image is of a good black and white character. Adurol is clean working, does not stain, and can be used over again. (See **Development**.)

Aerial Perspective. A term used to denote the idea of distance in a landscape (or photograph of the same), which depends upon the obstructive or dispersing influence of the atmosphere. The correct rendering of the "tone-values" of the composition depends largely upon the presence of, and adequate regard for, the aerial perspective.

Agar-Agar is a vegetable gelatinous material obtained from species of white seaweeds common on the coasts of Singapore and Straits Settlement. It has been suggested as a substitute for gelatine in photographic emulsion making.

Air-Brush is an instrument employed largely by professional photographers and others for working up and finishing photographs and enlargements in monochrome or colour. Air is pumped by means of a foot-blower through a tube into a small instrument similar in size and appearance to a pencil or fountain-pen. The point of this "brush" terminates in a chamber containing liquid colour, and at the extreme end is a fine orifice through which the colour is driven in a

very fine spray on to the picture. The strength and width of the line of spray is regulated by a movable needle in the orifice. This is actuated by finger pressure, which also controls the air passage. The spray of colour is directed like a paint-brush to the parts of the picture that require darkening or altering.

Albuminised Paper is the name generally applied to a form of printing-out-paper that has now been practically superseded by gelatino-chloride and collodio-chloride printing-out-papers. It is prepared by sensitising, in a nitrate of silver bath, paper that has been previously coated with albumen (white of egg) and a chloride in solution. The paper after printing under a negative is toned in a gold-acetate bath.

Alum. There are several varieties of "alum" known to chemists, but "potash alum" (the ordinary common powder alum) and chrome alum are the two employed in photography. The ordinary alum is used to harden the gelatine film of negatives or prints and to prevent frilling in hot weather. Chrome alum is used as a constituent in the manufacture of dry-plate emulsion. A five per cent. solution of alum is the usual strength for a hardening bath for prints or plates, or chrome alum, 1 ounce, water, 30 ounces, may also be used.

Amidol is diamidophenol. It is a very useful developer for plates, and is specially suitable for bromide paper on account of the fine black colour of the image produced. It has the property of developing without the addition of alkali and for this reason is sometimes recommended as an ideal developer in hot weather. In solution it will not keep well and soon loses its developing power. The developer should therefore be made up as required.

The following is a good formula:—

Amidol	50 grains.
Sulphite of soda	24 ozs.
Bromide of potassium	20 grains.
Water	20 ozs.

(See Development and Bromide Printing.)

Ammonia is a very volatile pungent gas known to photographers as "fumes" in water and termed liquor ammoniac fort. s.g. 880. It should be kept in a cool place in well stoppered bottles. The fumes should not be inhaled. It is used as the alkali in pyro-ammonia developer (q.v.). It is, however, unsatisfactory as a developer as its strength is uncertain.

Ammonium Bichromate. Made by neutralising chromic acid with ammonia. It is often used in place of potassium bichromate in processes depending upon the action of light on bichromatised gelatine, such as the carbon process and the oil process.

Ammonium Bromide. Used as a restrainer (q.v.) in development. Potassium bromide is now more frequently used for the purpose.

Ammonium Carbonate is used occasionally as an alkali in development.

Ammonium Sulphocyanide is used in conjunction with chloride of gold for toning gelatino-chloride printing papers. It is a very deliquescent salt and for this reason should be made into a 10 per cent. solution when quite fresh. It has a softening effect on gelatine. (See Toning.)

Amyl Acetate. A colourless liquid with a fruity smell. It is used as a solvent of pyroxyline in the preparation of celluloid and celluloid varnish. A good celluloid varnish for application could be made by dissolving 200 to 300 grains celluloid in 10 ozs. amyl acetate. (The celluloid may be old films with the gelatine removed.)

Anaglyph is a form of stereoscopic print in which one half of the pair of pictures is printed in one colour (red) and the other is printed over it in a complementary colour (green). The stereoscopic effect is obtained by looking at the print through two pieces of glass or coloured gelatine, one of which is coloured red and the other green. One eye looks at the green image through the red glass, the other eye sees the red image through the green glass.

Anastigmat, Anastigmatic, Atigmatism. Anastigmatism is a defect in photographic lenses whereby it is impossible to focus sharply vertical and horizontal near the margin of the field of view. It should not be

confounded with "curvature of field," as in this case the alteration of the focus will improve the marginal definition, though destroying the focus in the centre. An anastigmat lens is one free from astigmatism. The best forms of modern lenses are corrected for astigmatism. A simple test is to make a vertical cross of white paper (not too large) and focus it sharply in the centre of the ground glass screen of the camera. Then without refocussing, swing the camera on the tripod top until the small image of the white cross is at each end of the plate in turn. If the lens is corrected for astigmatism, the image should remain as sharply defined as it was at the centre (with lens at full aperture). If the vertical or horizontal arms of the cross are blurred, the lens has not been corrected.

Angle of View is the angle included by lines drawn from the lens to the edges of the plate it is covering when the image is sharply focussed.

Angle of Lens is determined by the focal length of the lens in relation to the size of plate with which it is used. Thus one lens of a given focal length may be used as a mid-angle lens, as the angle of view it embraces is larger or wider. A normal-angle or mid-angle lens is one of which the focal length is about the same as the diagonal of the plate it covers. Thus a 5-inch lens would be a normal-angle for a quarter plate (4½ in. x 3½ in.). If, however, the same lens is used on a half plate (5½ in. x 4½ in.), it becomes a wide-angle lens, as the angle of view it embraces is larger or wider. If the same lens is used on a 2½ in. x 3½ in. plate, it becomes a narrow-angle lens, as the amount of view included in the area of the plate is smaller and embraces a narrow angle.

Anhydrous means free from water. Many chemicals contain water in their composition which can be expelled on heating them sufficiently. If an anhydrous chemical is recommended in a formula and crystals are used instead, it is necessary to ascertain how much more of the crystals is required to have the same effect.

Animal Photography. (See Nature Photo-graphy.)

Aperture. The name given to a lens that has been corrected for spherical and chromatic aberrations.

Aperture is the term denoting the size of the diaphragm or opening in the lens through which the light passes to the sensitive plate. The entire surface of the glass of a lens is never used, the outer edge being cut off by the diaphragm or "stop" (q.v.).

Architectural Photography. The photography of architecture (houses, churches, cathedrals, &c.) both interior and exterior calls for a rigid camera with adjustments for rising front, swing-back, and wide-angle lens. It is usual to stop the lens down to obtain the finest detail and give fairly long exposure, using a backed plate. (See Halation.) To secure the best results the back of the camera must be perfectly perpendicular, no matter how much the front is swung or raised, otherwise the vertical lines of the building will, in the photograph, converge towards the top or bottom according to the direction of the swing. It is not wise to use a lens including too great an angle. A very wide-angle lens tends to give distorted perspective in architectural work. When photographing interiors a rough and ready rule that may serve as a guide for exposure is to focus with the open aperture of the lens. Then, with the head under the focusing cloth, stop down the lens until detail is only just visible on the ground glass. With a rapid plate ten minutes' exposure will be about right.

Aquaint. Another and earlier name for the gum-bichromate process (q.v.).

Aristotype a name applied to one particular make of gelatino-chloride paper but occasionally used as a general term to printing-out-papers with a base of collodion and gelatine.

Artificial Light Photography. (See Flash-light.)

Autochrome Plates are the invention of MM. Lumière of Lyons and are intended for the production of photographs in natural colours. The results are extremely true to nature but are, so far, only in the form of glass transparencies. Thus each exposure yields but one colour transparency. The photograph is pre-

duced with the aid of minute transparent starch grains which are stained—some blue-violet, some green, and some orange—the proportion of each being of course definite. These grains form a layer or substratum on the glass plate on which is then coated a panchromatic emulsion. An orthochromatic screen is used in exposing and the exposure is made through the glass side. In this way the colours of the image are filtered through the screen of coloured starch grains before reaching the sensitive film. The constituents of this screen permit certain colours to pass according as they approximate the colours of the starch grains. Exposure varies according to light and subject but as a rough guide one second at 1/8 at midday in summer sunshine for an open landscape subject will be about right (this is with the correct yellow screen in position on the front of lens). Other exposures can be calculated from this. The development needs two separate treatments. A negative is produced first and this is then reversed into a positive.

The latest instructions given by the makers are:

The developer recommended is:—

Distilled water 35 ozs.

Metuquinone (Quinomet) 1 oz.

Anhydrous soda sulphite 31 ozs.

Ammonia '900 90 drams

Potassium bromide 90 grains

Dissolve the quinomet in warm water (about 100), add sulphite, and then ammonia, when cold.

For use, take of the above solution 2 oz.

Water 4 oz.

Development must be conducted in darkness, and will be complete in 2½ minutes if exposure be correct, and the temperature of developer about 60° F.

A negative is produced by this method, and at the expiration of the time named, take the plate from the developer, rinse in running water, and place in a dish containing about 3 ozs. of the following solution:—

Water 35 ozs.

Potassium permanganate 30 grains

Sulphuric acid 3 drams

As soon as the plate is in this solution, the remaining operations may be conducted in white light. The plate, from being opaque, becomes clear, and the colours more and more visible by transmitted light.

After 3 or 4 minutes, when the plate is completely clear and shows no trace of negative image, it is taken from the dish and washed for about 30 seconds in running water. The plate is then re-developed in full daylight, using the same solution employed for the first development. When the high lights are completely darkened (about 3 or 4 minutes), the plate is washed for 5 minutes and placed to dry. Fixing is unnecessary, unless the plate is to be intensified. After the plate is quite dry, it should be varnished with the following special varnish:—

Crystallisable benzene 5 ozs.

Gum dammar 1 oz.

This is applied cold by flowing over the surface of the plate.

Other developers may be used for autochromes, and it is quite possible to control development and compensate for under or over exposure. It is best, however, to adhere as much as possible to the makers' instructions.

Azol. A patent one-solution concentrated developer that requires only the addition of water for use. Gives negatives of very fine quality and gradation, and works up detail in under-exposure. Azol is good also for bromide and gaslight papers and lantern slides.

Background. There are many kinds of backgrounds in photography, anything that is behind the principal figure or object in a picture may come under this name. Natural backgrounds are most pleasing, but for portraiture painted backgrounds or sheets may be employed. (See **Portraiture**.)

A pleasing plain background can be made with an ordinary blanket pinned up to avoid creases.

Brown cartoon paper (obtaining in long rolls and various widths) is also very useful for some subjects. The colour or tone of the background will affect the colour or tone of the figure or object photographed. Thus a dark background will make it look lighter than normal, while a white background will have the reverse

effect; contrasts should therefore be avoided, but a graduated background passing from dark on one side to light on the other—or diagonally, will be found handy for portraits. To prepare a home-made background, f.bleached calico of sufficient size should be stretched on a light deal frame, or if it is to roll up when not in use, the calico can be tacked to a convenient wall while being prepared. The following mixture should be freely printed over the surface:—

Common whitening 1 lb.
Glue powder 1 lb.
Tieacle 1 pint.
Water 1 gallon.

Mix thoroughly and add

Ivory black 2 oz.
Ultramarine 1 oz.
Red ochre 1 oz.

Ground down into a fine cream with water. It can be darkened or lightened according to the amount and proportions of colour added. The coating will dry lighter. The above gives a pleasing neutral colour of normal depth of tone suitable for most portraiture.

Backing Plates consists of coating the back of plates with some black or non-actinic substance to prevent halation (q.v.). The essentials of a perfect backing mixture are that it should reflect no rays of actinic light, and that it should be in absolute optical contact with the back of the glass plate.

The two following backing mediums are to be recommended:—

(1.) Amaline Black, bought in the form of a paste, is mixed with yellow dextrin and water to form a black paste. A little spirit is added to facilitate drying. This is spread thinly with a sponge on the back of the plate. This black backing is specially suitable for orthochromatic plates.

(2.) Gum water 2 oz.
Caramel 1 oz.
Burnt sienna in powder 1 oz.

Mix in a mortar. If too stiff add a little spirit, and spread over back of plate with sponge or pad of lint.

An old printing frame makes the most suitable holder for the plate during backing. It is placed in position, glass side out (in the dark room of course), a pad of perfectly clean blotting-paper is then placed in contact with the film side and the back put into position. In this manner the backing can be applied cleanly without soiling the fingers, and a dozen plates can be backed and put up to dry in a very short time. The first can be put into the dark slide or holder as soon as the twelfth is backed.

Most makers now supply their plates ready backed at a small extra charge. Backed plates should be used always if possible. The backing mixture can be removed with damp sponge previous to development.

Baryta Paper is pure paper coated with an emulsion of sulphate of barium, made partly insoluble by chrome alum. This is used as a support for gelatino-chloride printing-out emulsions and in collotype printing, etc.

Beach's Developer is a pyro-potash developer named after its inventor, F. C. Beach, of New York. The following is the formula:—

a. Hot distilled water 2 ozs.

Sulphite of soda 2 ozs.

When cold add:—

Sulphurous acid 2 ozs.

Pyro 1 oz.

b. Carbonate of potash 3 ozs.

Sulphite of soda 2 ozs.

Water 7 ozs.

For use mix 1 dram of a, 1 dram of b, and 1 oz. of water.

For over-exposure use more of a.

For under-exposure use more of b. (See **Development**.)

Bellows. The folding portion of the camera which unites the back and front portions is called the bellows and is usually made of blackened calico or leather. The folds have to be carefully designed and well constructed so that they close up evenly into the smallest possible space and are quite light-tight.

Slight damage to camera bellows can usually be repaired with black sticking-plaster—or with small pieces

of thin black kid glove applied with seccotine or glue.

Bichromate of Potash is a red coloured crystalline chemical which has the property of rendering many colloids—such as gelatine, gum, etc., insoluble, when the latter, after being treated with it, are exposed to light. It is used in the carbon, the gum-bichromate, the oil and the bromoil processes, also in the chromium intensifier.

Bird Photography. (See *Nature Photography*.)

Blacking. The interior of all cameras, dark-slides, and lens tubes should be coated with a dead black to prevent the reflection of light and consequent fog on the plate. A good black for the purpose can be made by grinding lamp- or ivory-black into a paste with japaners' gold size.

Another formula for blackening wood is as follows:—

Extract of logwood 1 oz.
Chromate of potash 30 grains.
Water 35 ozs.

Dissolve the extract in boiling water, add the chromate also in solution. This is a deep violet liquid which changes to black in contact with the wood.

To blacken leather-covered hand cameras which have become shabby apply the following mixture with a sponge:—

Glue 4 ozs.
Vinegar 14 pints.
Gum arabic 2 ozs.
Black ink 8 ozs.
Isinglass 2 drms.

Blanchard's Brush consists of a piece of swansdown calico doubled and fastened by means of an indiarubber band round the end of a strip of glass 2 inches wide and 6 inches long. It is used for applying various sensitising solutions to papers, giving a streak 2 inches wide, of evenly distributed solution with each sweep of the brush across the surface of the paper.

Blisters occasionally occur in printing papers in hot weather and very occasionally in plates. A bath of alum in solution will usually prevent blistering; formalin (1 part in 50 water) is also a preventative.

If blisters have already formed on the surface of bromide or printing-out paper, they may be reduced with a bath of methylated spirit.

Changes of temperature in different solutions when a print is being passed from one to the other is a frequent cause of blistering.

Blocking-out. A term used to describe the application of black, red, or other opaque paint to those parts of a negative that are not required, when the print is made. The parts that are "blocked out" do not allow the light to pass and remain white in the print.

Blue Print Process, called also "ferro-prussiate" or "cyanotype" process. This process, in which salts of iron are used for the production of the image, gives a picture of a bright blue colour. One method of preparing it, so that a positive image is obtained from a negative, is as follows:—Good smooth drawing paper is pinned on to a board and coated by means of a Blanchard brush (q.v.) with:

a. Potassium ferricyanide 75 grains.
Water 1 oz.
b. Ammonio-citrate of iron 96 grains.
Water 1 oz.

Mix equal parts of a. and b. for use.

Dry the coated paper in the dark and print under the negative in a printing frame in the ordinary way until the image is clearly seen of a greenish colour. The prints are then well washed in plain water till the high lights are quite white. Rinse in hydrochloric acid 1 dram, water to ozs., and then again in plain water. The print is then dried. The process, on account of its cheapness and ease of making, is largely used by architects and engineers in copying plans and tracings, etc.

Boiling Silk or Cloth is a fine-mesh translucent fabric used in photography for diffusing both light and definition of detail when making enlargements. Interposed between the lens and the bromide paper various degrees of diffusion or softening of the image

can be introduced according to the distance from the paper. It is best stretched on a light frame for use.

Books on Photography. There are a great number of books on photography that should be read by the serious worker who wishes for further instruction in the art. The following is a selection of some of the best:—

For the Beginner:—

"How to ensure Correct Exposure."
"To make Bad Negatives into Good."
"Development made Easy."
"Home Portraiture made Easy."
Price 4d. each. (Published by Hazell, Watson and Viney.)

The Text Book for general information and reference on everything photographic:—

"The Dictionary of Photography." Price 7s. 6d. (Hazell.)

For Special Branches of Photography:—

"Practical Pictorial Photography" (Hinton); price 2s.

"Lantern Slide Making" (Lambert); price 1s.

"Bromide Printing" (Lambert); price 1s.

"The First Book of the Lens" (Piper); price 2s. 6d.

"Chemistry for Photographers" (Townsend); price 1s.

"Photography on Tour"; price 6d.

"First Steps in Photo-micrography"; price 1s.

"Photography with Roll and Cut Films" (Hodges); price 1s.

"The Perfect Negative" (Lambert); price 1s.

"Finishing the Negative" (Ward); price 1s.

"Retouching" (Hubert); price 1s.

"Toning Bromides" (Somerville); price 1s.

"Carbon Printing" (Wall); price 1s.

"Platinotype Printing" (Hinton); price 1s.

"P. O. P." (Hinton); price 1s.

"Marine Photography" (Mortimer); price 6d.

"Portraiture without a Studio" (Lambert); price 1s.

"Making Enlargements" (Smith); price 1s.

"Development and Developers" (Brown); price 1s.

"Flashlight Photography" (Mortimer); price 1s.

"Hand Camera Work" (Kilbey); price 1s.

"Photography for the Press" (Ward); price 1s.

"Photography of Coloured Objects" (Mees); price 1s.

"The Oil and Bromoil Processes" (Mortimer and Coulthurst); price 1s.

Broken or Cracked Negatives can generally be printed from if the gelatine film is not broken as well as the glass. First, to prevent further fracture, cement a clean piece of glass (same size) to the glass side of the broken negative. This can be easily done by applying small spots of seccotine or fish glue to the corners, pressing the two surfaces together, and allowing to set hard under light pressure (such as a book placed on top). The negative should then be printed from in an ordinary frame, but should be placed at the bottom of a deep box so that vertical light only strikes the cracked surface. An alternative is to place the printing frame in a shallow tray suspended by strings from the corners. If the tray is then rotated while the negative is printing, the crack will scarcely show in the print. The same principle may be applied in a modified form to bromide or gaslight printing, or the film may be stripped from the broken glass and transferred to another plate. (See *Stripping*.) If both the film and glass are broken the first method is best, taking care to assemble the pieces carefully and in exact register on the surface of the new glass, using a spot of, or a drop of, Canada balsam for each piece. If the cracks still show, and the negative is a valuable one, an enlargement should be made from it, the cracks carefully painted or worked out, and the enlargement then copied to make a new negative. A positive may also be made from the broken negative and a new negative made from it after careful retouching.

Bromide Paper and Printing. Bromide paper is paper coated with an emulsion of bromide of silver in gelatine, with or without other silver haloids, and is

used for obtaining prints by development either by contact printing or enlarging with daylight or artificial light. There are a great number of bromide papers on the market, and obtainable from all photographic dealers. They vary only in surface textures (glossy, matt, smooth, rough, etc.), and slightly in speed. The paper is sold in packets and rolls. Packets of cut sizes are most convenient to handle. It should be opened and used in the dark room in yellow or orange light. The sensitive surface is easily seen by the tendency to curl inwards. If further evidence is needed, the corner of the sheet may be nipped between the teeth; the sensitive (or emulsion) side will stick to the teeth.

For contact printing the paper is placed in a printing frame with the negative, sensitive side to the film of the negative in the same manner as for daylight printing with P.O.P. (q.v.). The loaded printing frame is then taken out of the dark room and exposed to gas, electric, or lamp-light, or the white light may be turned up in the dark room (take care that the remainder of the bromide paper in the packet is covered up).

The exposure varies according to the intensity of the light, the distance of the negative from the light, and the density of the negative. The speed of the paper also affects the exposure. The makers' instructions, given with each packet of paper, should therefore be followed as to correct exposure, or trial prints may be exposed and developed until the right time is ascertained. As a rough guide, with a negative of average density, an exposure of fifteen to twenty seconds may be tried at a distance of 18 inches from the light of an ordinary fish-tail gas burner, or four to eight seconds with an incandescent burner. The worker should try to work with the same light and always at the same distance from it; by this means, when the varying densities of negatives are gauged, good prints can be made with every exposure.

Development of the print is conducted in the dark room. Prints up to and including 10 x 8 inches can be placed dry in a developing dish and flooded at once with the developer. Larger prints should be soaked first in plain water, taking care in both cases to avoid air-bell-forming on the surface. If the print is over-exposed, the image flashes up quickly and soon goes grey and dark all over, with no contrasts. If it is under-exposed, the image appears slowly, and the shadows clog up and get very black, while the highlights remain thin or light. If correctly exposed, the image will come up gradually and evenly, the shadows first, then the half-tones, and finally the details in highlights. The dish is rocked during development, and when the print is fully developed (this is best ascertained by looking through the print, not at it), it is fixed, washed, and dried.

Developers for Bromide Prints. One of the best developers for bromide paper is amidol. This gives fine black tones, and is easy to make up. A good formula is given under Amidol (q.v.). Another good formula for a developer that keeps well and gives good tones on bromide papers, is:—

Metol	8 grains.
Hydroquinone	30 grains.
Sulphite of Soda	1 oz.
Carbonate of Soda	1 oz.
Potassium Bromide (10% solution)	20 minims.
Water	20 ozs.

Dissolve in the order given, and use a sufficient quantity for the print. This developer may be used for several prints, but it should be remembered that stale developers will produce stains, and developers in which there is an excess of bromide will produce unpleasant muddy tones, especially if the prints are over-exposed.

After development the prints are fixed in

Hypo	4 oz.
Water	1 pint

or the hypo-metabisulphite fixing bath given under "acid-fixing" (q.v.). Fix the prints for ten minutes and then wash well in running water (or several changes) for one hour.

To ensure success in making bromide prints, the exposure should be correct, the dark-room light should be safe (otherwise the prints will be fogged), the dishes, etc., should be kept clean, and the developing dish

never used for fixing and *vice versa*. Contamination with hypo on the surface of the prints or in the developer should be avoided, or marks and stains will result. The hypo bath should be about same temperature as developer, or blisters may occur.

For making enlargements and toning bromides, see **Enlarging and Toning**.

Bromoil is the name of a process for the production of photographic pictures in oil-pigment upon a base consisting of a bromide print or enlargement. The outlines, details, and masses of the original photograph are retained, but the tones can be darkened or lightened generally or locally at the will of the operator and the success of the final picture depends upon his artistic skill. The procedure is as follows:—A bromide print of good quality (fully exposed and developed—preferably in amidol developer) is bleached in the bromoil bleaching solution sold by all dealers for the purpose, or the following may be made up:—

Ozobrom stock solution	4 parts.
10 per cent. potash alum solution	4 parts.
10 per cent. citric acid solution	1 part.
Water to make	20 ozs.

An alternative formula is:—

Potassium bichromate 10 per cent. sol.	2 parts.
Potassium bromide	1 part.
Potassium ferricyanide	1 part.
Alum	4 parts.
Citric acid	1 part.
Water	10 parts.

In any of these bleaching baths the black colour of the bromide disappears leaving only a faint yellow image. The print is then rinsed and placed in

Water	1 pint.
Sulphuric acid	1 oz.

(Note.—Add the acid to the water and not *vice versa*.)
Allow the print to remain in this for five minutes.
Then again wash and fix in

Hypo	2 ozs.
Sulphite of soda	1 oz.
Water	20 ozs.

Finally, wash again and place the print on a pad of wet blotting paper when it is ready for pigmenting, or it may be hung up to dry and then re-wetted at some future time for pigmenting when required. The pigmenting is conducted with special fish and hog-hair brushes in the same manner as in "Oil-printing" (q.v.). **Bulb Exposure.** Every instantaneous shutter, that is fitted with a pneumatic ball and tube arrangement for actuating the mechanism, can be kept open at will by pointing the index of the shutter to "B" (bulb) and keeping a steady pressure on the India-rubber ball. The term "bulb exposure," i.e., keeping the shutter open at will, is now also used with shutters that have no pneumatic release.

Burnishing is the operation of drawing prints over the surface of a heated bar. A burnisher for photographic prints is constructed somewhat on the principle of the household mangle, but with the lower roller stationary. The surface of the prints (the prints are mounted on card) is lubricated with a solution of fine grains of Castile Soap dissolved in an ounce of methylated spirit. This is rubbed over the print with a sponge. Burnishing is generally done by professional photographers. For other methods of applying a high gloss or glaze to photographs see **Enamelling and Glazing**.

Calcium Chloride, a chemical that has the property of rapidly absorbing moisture from the air. It is used in photography for drying the air in preservative boxes in which platinum type paper is kept. When the calcium chloride has absorbed a certain amount of moisture it becomes damp itself. When this occurs it should be baked on an iron shovel in a hot oven until dry again and ready for further use. A calcium tube or box is the term applied to the receptacle in which platinum type or carbon papers are kept. The air within is kept perfectly dry by means of pieces of calcium chloride in the bottom of the tube or box.

Camera. The term is now so well known as hardly to need a definition. It is an apparatus consisting of a light-tight box with a lens or its equivalent at one

end and place for the light sensitive plate or film at the opposite end. The image of external objects is projected by the lens on to the screen or plate within the camera. In form it may be a wooden-sided box, leather covered or polished, or it may consist of merely the back for the plate and the front for the lens connected with a light-tight collapsible bellows and held apart by struts or a baseboard, both of which will fold up when the apparatus is closed. Cameras may be divided roughly into three groups: (1) stand cameras, (2) hand cameras, and (3) hand and stand cameras combined (*q.v.*).

Caramel, a form of burnt sugar used in photography for backing plates in the prevention of Halation (*q.v.*).

Carbon Process. This process consists of the formation of the photographic image in carbon or coloured pigment mixed with bichromatised gelatine. It depends upon the action of light on gelatine which has been treated with bichromate of potash or ammonium. Gelatine so treated becomes insoluble when exposed to light. If coloured pigment is mixed with the gelatine, which is then treated with bichromate, and paper is coated with the mixture, a sensitive surface is produced that, when exposed under a negative in a printing frame, will reproduce all the gradations of the negative in degrees of varying insolubility according to the relative densities of the image. As the surface of the pigmented gelatine is dark no visible image can be seen when printing, and it is therefore necessary to use an actinometer to time the correct exposure, or the time taken to print a piece of P.O.P. under a similar negative may be taken as a guide. The negative must be given a "safe-edge" before printing. This is a narrow band of black paper stuck round the extreme edges of the negative and prevents the picture filling up in development. To make the positive or print it is necessary, however, that the pigmented gelatine, or "tissue" as it is called, should be transferred to another support before development. Development is conducted with hot water only, and the object is to dissolve away all those portions of the tissue which were unacted upon by light and remain soluble, leaving only the picture which is formed of the insoluble tissue. It is obvious that as the light acted upon the sensitive tissue from the top downwards the upper portions become insoluble first and development or washing away of the soluble parts must proceed from the bottom. To achieve this the tissue, after printing is complete, is placed face to face with a piece of "transfer" paper (sold for the purpose) and both are immersed in cold water until the first tendency to curl has ceased and the tissue remains flat. They are then withdrawn, still face to face, and vigorously squeezed into perfect contact. They are then placed between blotting boards for five or ten minutes under pressure (a large book will do) and immersed in a bath of water at a temperature of 105° or 110° F. When the pigmented gelatine begins to ooze out at the edges of the paper, strip off the paper upon which the gelatine was originally spread and keep washing the print which remains on the transfer paper with the hot water by throwing the hot water on to it with the hand or by means of a cup or small soft sponge. As soon as development is complete, and the picture remains perfectly clear upon its new support, it is plunged into a bath of cold water to set the gelatine and then placed in a bath of the following:—

Powdered Alum 1 oz.

Water 30 ozs.

This bath fixes the print and clears it also. The print is finally washed in several changes of water and hung up to dry.

This process is called "single-transfer," and it is obvious that the picture so produced is reversed right and left. For many subjects—such as landscapes, etc., this does not matter. But if it is desired to have the picture right-way round the print must be re-transferred, and this is called "double-transfer." In this case the first development of the print must be conducted on a waxed "temporary support" (obtainable from all makers of carbon tissues). The

procedure is the same up to the final washing. The wet print is then brought into contact with a piece of "final support" under the surface of water, and complete contact secured by squeezing and putting under pressure until dry. When dry, the temporary support is stripped off and the picture remains right way round on its final support. The final support may be paper of any texture, and almost any hard-surface material—such as wood, ivory, etc., may also be used. It is prepared by coating with a substratum of Nelson's gelatine, 1 ounce; water, 20 ounces. When dissolved (with heat) add to it gradually 12 grains of chrome alum dissolved in 1 ounce of water. The commercial final support—which is supplied in great variety by the makers of the tissue—merely requires soaking in alum solution, 1 ounce to the pint, an hour before using.

Carbon tissue can be bought either "sensitive" and ready for immediate use, or "insensitive," when it requires sensitising in—

Potassium bichromate 4 drs.

Citric acid 1 dr.

Water 25 ozs.

Ammonia (880)—sufficient to turn the liquid a

pale yellow colour (about 3 drs.).

The insensitive tissue is immersed in this for two minutes in hot water, or three minutes in cold. It is then hung up to dry and kept protected from light, air, and damp. The tissue when sensitised (either bought or home-made) will not keep long. The tissue when printed has a continuing action, and the printing will go on even after it has been taken out of the printing-frame and placed in the dark. Development should therefore be undertaken soon after printing.

Celluloid, a transparent material, the chief constituent of which is pyroxyline or gun-cotton. It dissolves in amyl acetate or acetone and forms a useful varnish. It is chiefly used in photography as a substitute for glass, and as the base for "cut films," "roll films," and "film packs" is familiar to every amateur. It is also used as the base for cinematograph films, and when coloured is employed for the production of developing dyes, etc. It is very inflammable and must not be used near a naked flame.

Cardinal. A trade name applied to a concentrated one-solution developer for Plates, Films, Papers, and Lantern slides.

Changing Bag. A very portable form of dark tent used for changing sensitive plates in daylight. As a convenient accessory for the outdoor photographer it is very useful. The bag is usually made of several thicknesses of opaque material and is shaped somewhat like a pillow-case with sleeves. The dark-slides and plates are inserted into the bag, the hands of the operator are introduced through the sleeves, which fit closely to the arms, and the plates are changed inside the bag in perfect darkness by sense of touch only.

Chloride of Gold. Used in making the gold-toning baths for various silver printing-out papers. It is sold in small 15 or 71 grain tubes, the contents of which should be dissolved in 15 or 71 drams of water.

Chromatic Aberration. Every simple single lens suffers from this defect, which is due to the fact that rays of light of different colours are refracted at different angles; and each differently coloured ray of light that goes to build up a picture has a different focal length. Moreover, the principal "visual" rays are focussed further from the lens than the "chemical" rays. Chromatic aberration is corrected by combining one lens with another of different power so as to bring the principal visual and chemical rays to the same focus.

Cinematograph. An apparatus for the projection of animated pictures. The pictures are taken in a special machine on a continuous film at the rate of about twenty per second. The pictures are projected on to a screen—magic lantern fashion—by means of a lens and strong light enclosed in the apparatus, and the effect of motion is given to the incident depicted by the rapid sequence of continuous series of succeeding exposures taken of the original subject. As each separate picture in the series is brought before the lens, a revolving shutter uncovers it and allows the light to

strikes through, the shutter then covers the lens for a fraction of a second at the instant when the film is moved on, and the following picture of the series is then uncovered. This is repeated with great rapidity, and the retention of vision assists in giving an impression of the continuing action rather than any individual phase of it.

Clearing Bath. When negatives become stained in development, a clearing bath is sometimes necessary to remove the stains. The following is a good formula:

Alum 2 ozs.
Citric acid 1 oz.
Water 20 ozs.

The alum may be replaced with 1 oz. of chrome alum. This has a tanning effect on the film, and is especially useful for pyro-developed negatives, changing the yellow stain into a fine olive-green. (See also **Thioarsbamide**.)

Cloud Negatives are produced most readily on orthochromatic plates used in conjunction with a yellow light filter. Strongly marked clouds may, however, be easily photographed on ordinary plates, using a fairly small stop and rapid exposure. The utility of cloud negatives for printing suitable skies into landscape subjects is great (see **Combination Printing**), but great care must be taken that the lighting of the landscape and that of the clouds printed in is from the same direction. Cloud negatives should not be too dense, but rather on the thin side and full of delicate gradation. A soft working developer, such as rodinol or metol, is most suitable.

Colloidio-Chloride printing-out papers are similar in many respects to the familiar gelatino-chloride P.O.P., but are made with a colloid base for the sensitive emulsion instead of gelatine. These papers (sometimes known as C.C.) are printed out under a negative in daylight, and are toned and fixed as in the case of gelatino P.O.P. (q.v.). They are also made "self-toning," and need fixing only. One great advantage of C.C. paper is its hard surface. It can be dried between blotters or in front of a fire if prints are wanted quickly.

Colloidion is used in wet-plate processes, and also in preparing an enamel surface for prints. It is made by dissolving pyroxyline (gun-cotton) in a mixture of equal parts of alcohol and ether.

Collootype is a photo-mechanical process by which prints in a greasy ink are obtained by means of a film of gelatine used as a printing surface. The picture is produced in the gelatine by the action of light through a negative—the gelatine being previously treated with bichromate of potash. After exposure, the film of gelatine is washed and inked with the greasy ink by means of a printer's ink-roller. The ink adheres only to those places which have been affected by light. By using a suitable press, many proofs can be obtained.

Colour-Sensitive. (See "**Orthochromatic**.")

Colouring Photographs. There are many special sets of tints sold by all photographic dealers for the purpose of colouring or tinting photographs. These are mostly aniline dyes in solution, and are applied in thin washes with a brush direct to the surface to be coloured. Aniline dyes—obtained in crystals of almost any colour—dissolved in water to which a drop of liquid oil of gall and a little gum arabic have been added, will serve the purpose well. Ordinary transparent water colours can also be used. A little oil of gall in gum water serves as a medium, and overcomes all tendency to greasiness that occurs with some prints. Several thin washes of colour applied evenly are better than one full wash. Ordinary oil colours thinned with methyl and turpentine can also be used effectively on glossy surfaced prints. Use the transparent colours only. The air-brush is also an effective method of applying colours. (See **Air-Brush**.)

Colour Photography. The Autochrome process (q.v.) is at present the most satisfactory and successful form of direct colour photography. There are several other somewhat similar processes, all of which appear to be founded on the same idea of a screen plate, and the results are all in the form of colour transparencies. Colour photography on paper is still only possible in a satisfactory manner by means of the

three-colour process. This necessitates the taking of three separate negatives of the subject through three different colour screens (red, blue-violet, and green). Prints from these three negatives are produced in the primary colours, superposed on one piece of paper, and in combination reproduce the colours of the original.

Colour Screen. (See **Light Filter**.)

Combination Printing. It is frequently necessary in the production of a pictorial photograph to combine the best or most effective portions of two or more negatives to make an effective whole. To do this successfully requires both skill and knowledge, otherwise results may be produced that betray their method of production too clearly. The most general application of combination printing is the addition of clouds from a suitable sky negative to a landscape subject. This is done by covering over—or masking—the sky portion of the landscape negative by means of a piece of opaque paper, the edge of which follows the general outline of the horizon. The landscape or foreground portion of the picture is then printed, and the negative is replaced with the sky negative. The print is arranged under this, so that the sky comes in the portion left blank, and the landscape part is now protected by masking with another piece of opaque paper in the same manner as the sky was protected before. The paper masks are then placed to the front of the printing frame, and printing should be conducted in diffused daylight, so as to secure as soft an outline as possible. In this way it is possible for the landscape and sky portions of the picture to be printed on the same piece of paper without showing a join. Foreground, middle distance, distance, and sky, can, if necessary, be printed from four separate negatives in this manner. Great care should be taken, however, to see that the lighting of the sky and landscape is from the same direction. The same method can be applied in making enlargements. The masks are then used between the lens and the easel on which the image is projected. The margins of the horizon must be marked in pencil on the bromide paper as a guide for the second printing.

Combined Bath is the name given to a toning bath which is combined with the fixing agent, i.e., hypo.

A simple but good formula is:—
Ammonium sulphocyanide 15 gra.
Sodium chloride 30 gra.
Hypo 2 ozs.
Water 10 ozs.
Add little by little:—
Gold chloride 1 gr.
Water 2 oz.

There are many other formulae for combined baths, but they are not generally recommended on account of the possibility of sulphur toning and consequent fading. (See **Toning**.)

Composition is a term denoting the grouping of the parts of a picture so as to form a pleasing and harmonious whole. Composition in the strict sense of the word simply means placing together (com-together; position-placed); but the artist by this word means a good deal more than merely putting things together, as one might put a row of books together on a shelf. The artist thereby means: (1) selecting some things and rejecting others, and (2) arranging the things selected in such a way as to express an idea, e.g. strength, grace, activity, repose, &c. Further information on this large subject will be found in the books devoted to pictorial photography. (See **Books**.)

Concave, Concavo-convex, etc. Concave is the term applied to the inner side of a curve or the inner curved surface of a lens. Concavo-convex means that one side of a lens curves inwards and the other side bulges out (convex). If one side dips in and the other side is flat this is called plano-concave. A double concave lens is one in which both sides curve in and the lens is thinner at the middle than at the margins. This form of lens is called a "negative" lens.

Condenser is the name of a combination of lenses mounted in a metal cell, which have for their purpose the condensing or collecting of rays of light which would otherwise be scattered and lost. These rays of light from a source of illumination behind the condenser

are then thrown forward in a beam of parallel or slightly convergent rays. A condenser is a necessary part of every optical lantern ("magic lantern") and artificial light enlarging apparatus. By its beams the light of the illuminant inside the lantern is collected and thrown forward through the transparency or negative in the most evenly distributed manner and with the greatest intensity. The usual form of lantern condenser is two plano-convex lenses mounted in a brass ring or collar with the convex surfaces nearly touching, and the flat surfaces outwards. (See **Lantern**.)

Conjugate Foci. The distances from object or original (in copying) to lens, and from lens to focussing screen or plate. In enlarging, the distances from negative to lens, and from lens to bromide paper are the conjugate foci of the lens.

Contrast is the term usually applied to a negative or print in which the densities of high-light and shadow are very abrupt, *i.e.*, without much half-tone. Contrast can be reduced in a negative by a selective reducer such as ammonium persulphate, or in a print by "sunning down" the high lights, or staining the paper. (See **Reduction**.) Contrast is generally present in under-exposed negatives.

Convex. The opposite to concave. The outside of a curve, *i.e.*, the surface of a lens that "bulges" out. (See **Concave**.)

Copper Toning. (See **Toning**.)

Copying Photographs can be conducted by either daylight or artificial light, the chief thing to watch being the evenness of the lighting. The camera must be so arranged that the picture to be copied is parallel with the focussing screen of the camera, both vertically and horizontally. Unless this is done the lines of the copy will not be straight. The lens should point to the middle of the original, and if the picture has a glossy surface the lighting should be so arranged that there are no reflections. A wall at the back of a well-lit room is a good position for diffused light, while a couple of incandescent burners, one on each side of the picture, and well shielded from the lens, will serve for copying at night. Focus with a large stop in the lens, and then stop down to get maximum sharpness. Orthochromatic plates should be used, and if the original has colour, a colour screen should be employed. The plates should not be too rapid. Exposure should be full, and can be ascertained only by trial. As a rough guide, with medium speed plate and stop $f/16$ in a brightly lit room, half a minute's exposure may be sufficient. Development should be conducted with a clear working developer, such as metol-hydroquinone (*q.v.*).

Cracked Negative. (See **Broken Negative and Stripping**.)

Crystoleum. A method of obtaining coloured photographs on glass. The process consists of squeezing a silver print in optical contact with a piece of glass, rendering it transparent, and applying paint or other colours to the details of the picture (the colours are applied to the back and show through the transparent photograph); then applying broad masses of colour to a second piece of glass, which is bound up with the first. When viewed from the front the effect, if the painting has been well done, is that of a photograph in natural colours.

Curvature of Field. In a single or uncorrected lens the rays of light do not come to a focus at the same time on a plane surface—such as the surface of a dry plate—but fall along a curve having the centre of the lens as its centre, and the focal length of the lens as its radius. To secure sharpness of focus at all points with such a lens, the plate would have to be concave, or saucer-shaped. Lenses with curvature of field will give an image sharp in the middle but blurred at the edges, or sharp at the edges and blurred at the centre, according to the distance of the focussing screen from the lens. This form of aberration is corrected in the better class lenses.

Daguerreotype. The earliest practical method of obtaining a direct permanent photograph of a person or an object. Invented by Daguerre, hence "daguerreotype." The process consisted of exposing (in a camera) a silvered copper plate, previously subjected to the action of silver iodide and silver bromide, and then

developing the image by exposure to a bath of mercury. The picture was fixed in a bath of cyanide of potassium and toned in hyposulphate of gold. The exposure usually extended to twenty minutes or half an hour, in bright sunshine.

Dark-Room. The room in which all operations requiring actual handling of the sensitive plates or films used in photography must be conducted. It is usually lighted by a "dark-room lamp" in which oil, gas or electric light is used. The light is filtered through a red, orange or other non-actinic medium (glass or fabric). Dark ruby glass is generally safe for all but colour-sensitive plates which require special "safe-lights," yellow or orange medium is sufficiently safe for bromide paper and lantern plates. Safe-lights specially manufactured for dark-room lamps are now obtainable from all large dealers and should be used in preference to "home made" varieties. The general arrangement of the dark room depends largely upon its size. It should be well ventilated (see that the ventilators do not admit light as well as air), and if possible water should be laid on. A lead lined deep sink for developing is very convenient, and racks should be fitted for storing dishes, etc. There should be plenty of shelves within handy reach for bottles, and all bottles should be plainly labelled so that they can be read by the light of the dark-room lamp. Provision should be made for turning on white light for printing bromide paper, &c. and if sensitive materials, such as plates, papers or films are stored in the dark-room, they should be kept in a dry corner below any gas burners, otherwise the fumes which ascend will soon spoil them. The dark-room light should be tested from time to time by leaving a dry-plate on the work bench in full view of the light but with half of the plate covered up. If the light is safe no trace of fog should appear on the exposed half when the plate is developed.

Dark-slide is the name given to the piece of apparatus containing the dry-plate used in the camera when making an exposure. It may be "single" when it is made to hold one plate only, or "double" when containing two. The first is usually made of metal, the latter of wood with wooden or metal draw-shutters. It is called "book-form" when it opens like a book and a plate is placed one on each side. Dark-slides are sometimes termed "plate-holders."

Deliquescent. This term applied to a chemical substance means that it is liable to become liquid on exposure to the air.

Depth of focus or "depth of definition" is the term applied to the distance between the nearest and most distant objects in a view that are rendered in sharp focus at the same time. A long-focus lens with large aperture has less depth of focus than a short-focus lens with small aperture. All lenses of the same focal length and working at the same aperture have the same depth of focus.

Developing Machine and **Developing Tank.** Mechanical contrivances for holding a number of films or plates in a vertical position during development. The film- or plate-holder stands in a tank or metal box containing the developer, and development is conducted automatically. (See **Stand and Tank Development**.)

Development and Developers. Development is the production of a visible picture or image in dry plate, film, or sensitive paper by chemical means from an invisible or latent impression. As applied to the production of a visible image on a plate coated with sensitive emulsion, that has been exposed to light in a camera, development consists of the application of a "developer." The developer is generally made up of (1) the developer proper; (2) the accelerator, which hastens the action of the developer; (3) the restrainer; and (4) the solvent or water. The developing agent may be pyro, hydroquinone, metol, amidol, etc. (*q.v.*). The accelerator is usually an alkali, and the restrainer is usually a bromide. Development is conducted in the dark-room (*q.v.*). The plate or film is placed in a flat-bottomed developing dish, and the developer poured over it, with a sweeping action, so that air-bubbles do not form on its surface. The plate should be protected as much as possible from the rays of the dark-room lamp, and the

dish should be rocked so that the developer is kept in constant motion. After a time, if the plate has been correctly exposed, the image will begin to appear and gain density. With some developers, such as metol, rodinol, etc., the image flashes up quickly, but takes some time to gain density. With other developers, such as pyro-soda, the appearance of the image is more gradual. If the plate has been over-exposed, the image will come up quickly in any case. If this happens, it should be quickly washed in plain water, and some restrainer (bromide of potash in 10 per cent. solution) added to the developer, and development continued. If the plate is under-exposed, it will take a very long time for the image to appear, and then perhaps only the high lights will come up (as black patches in the negative). In this case, more accelerator should be added to the developer, and an extra quantity of water also, to dilute it. When development is complete, the plate is rinsed and placed in the fixing bath (q.v.). Correct development can only be determined by experience, but generally it is safe to continue until the high lights are clearly seen as dark patches at the back or glass side of the negative. For developers see **Pyro**, **Metol**, **Hydro-quinone**, **Amidol**, **Rodinol**, **Azol**, **Adural**. See also **Stand development**, **Tank development**, **Time**, **Development**, **Films**, **Bromide paper**, and **Galathee paper**.

Diaphragm, or stop, are the metal or ebonite plates with a central opening used in a lens to cut out marginal rays and enable the middle portion only to be employed. Waterhouse stops are thin metal plates with circular openings of certain diameters. These are inserted in a slot cut in the barrel of the lens. Iris diaphragms consist of a number of very thin leaves of metal or other stiff opaque material opening and closing circularly to various sizes in the centre of the lens mount between the front and back combination. These are the two kinds of diaphragms most frequently met with, and their sizes of openings or "apertures" are determined by the focal length of the lens to which they bear a definite ratio. The usual markings of stops are $f/5.6$, $f/8$, $f/11$, $f/16$, $f/22$, $f/32$, $f/45$, $f/64$. These signs mean that the apertures are $f/5.6$ th, $f/8$ th, $f/11$ th, $f/16$ th, $f/22$ nd, $f/32$ nd, $f/45$ th, and $f/64$ th of the focal length of the lens. These apertures have also a settled ratio one to the other, and it will be found that the area of any one is just one-half of the next larger, and consequently lets one-half the amount of light through the lens to the plate. It therefore follows that double the exposure will be required for, say, $f/11$ than for $f/8$, or half the exposure required for $f/16$, and so on. This ratio is useful to remember when the correct exposure for any one stop has been ascertained. A smaller stop inserted in the lens increases the depth of definition, and is necessary sometimes when considerable detail is wanted, but the proportionate increase of exposure with the smaller stop should not be overlooked. The U. S. or "Uniform System" of stop marking is used by some lens makers, and the stops are marked 2, 4, 8, 16, 32, 64, 128. These indicate the ratio of exposures, and the actual f values are $f/5.6$, $f/8$, $f/11$, $f/16$, $f/22$, $f/32$ respectively. For general use the following maxims should be remembered:—A large stop gives a bolder picture than a small one—the masses of the picture are seen rather than fine detail. Focus with the largest aperture, then insert smaller diaphragms until the desired sharpness is obtained. The smaller the stop the longer the exposure, also the flatter the field of the lens and the greater the depth of focus (or depth of definition).

Diffusion of Focus can be produced in various ways: (1) By optical means in the construction of the lens itself, and a picture in which the details and outlines are softened and the masses broadened is obtained; (2) It can be brought about by putting the lens out of focus; (3) or by the obstruction of some translucent material when making the print, printing through the glass side of the negative, interposing a piece of film or glass between negative and sensitive paper when making contact prints, or by the use of **Bolting Silk** (q.v.) when making enlargements.

Distortion occurs in a photograph when (1) a lens

of too short focus has been used; the perspective in this case is distorted. (2) When the camera has been tilted in taking architectural pictures or copying subjects in which there are straight vertical lines. The lines in such a case will converge towards one end of the picture. (3) When a single lens is used for subjects containing straight marginal lines, these will be bent outwards or inwards at the ends according to the position of the stop in the lens.

Double Extension is the term applied to a camera that can be extended double the focal length of the normal lens used with it.

Doublet. A term applied to a lens that possesses two combinations or separate lenses (usually similar in construction) mounted at opposite ends of the lens tube; one lens correcting aberrations of the other.

Dry-Mounting is the name given to a form of mounting photographs in which the prints are mounted dry on to cardboard or paper mounts with the aid of special tissue and heat. The tissue is prepared with a coating of shellac on both sides, and is first affixed to the back of the print with a touch from a hot iron. Both print and tissue are then trimmed together and placed on the mount in the correct position. Print and mount are then put under even pressure between two hot plates, the shellac on the tissue melts, and the print firmly adheres to the mount without cockling.

Dry Plates. Glass of certain specified size coated with a film of gelatine in which a sensitive salt of silver is emulsified. These can be bought commercially so perfect in preparation and so cheaply that it is not worth while to attempt their manufacture at home. The dry-plate which varies in speed from slow or "ordinary" to extreme rapidity becomes the negative after exposure in the camera and development and fixing. (See **Development** and **Slides**.)

Enamelling Prints. This is done by coating the finished print with a film of collodion to give it a brilliant surface. The procedure is as follows: Clean a glass plate perfectly (an old negative will do) polish with French chalk and coat with:

Pyroxyline 10 grains.

Methylated Alcohol 1 oz.

Ether 1 oz.

Having made a solution of gelatine 10 grains to the ounce of distilled water, slip the collodionised plate and the print carefully into the solution of gelatine, avoiding air bubbles; bring the print face downwards into contact with the coated plate, remove from the solution, and squeeze into optical contact, and allow to dry. When thoroughly dry, raise one corner with a knife and the print will strip from the glass bearing the collodion film with it. (See also **Glazing Prints**.)

Encaustic Paste. A paste used to give "sun face" to the finished print. Useful for producing a slight gloss on dull or matt surfaced prints, especially in the shadows. Dissolve gum elemi in oil of lavender and add white wax previously dissolved in the same solvent. The proportions should be such as to yield a firm pouce. Apply to the print with the finger and then polish with a soft rag.

Enlarging is the operation of obtaining a larger image of a negative or positive upon some sensitive surface such as bromide paper. It may be done by daylight or by artificial light, in an enlarging camera or by projection of the image on to an easel. The negative that is enlarged from should be sharp in detail, and not too dense or with strong contrasts. The operation of enlarging tends to increase contrast and magnify other faults. A thin negative with plenty of good gradations and detail gives the best enlargement. The great number of small cameras that are now used renders some form of enlarging almost a necessity if prints of any size are required. The negative must be fixed up so that it is evenly illuminated from behind. The simplest method of enlarging is to place the negative in position in the back of the camera with which it was made. Have the back of the camera open so that light can be freely admitted. Place the back of the camera against a hole cut in a shutter that entirely blocks out the light of a window. Fix the camera on a shelf in front of the hole, so that the only light that enters the room is through the camera. The camera thus acts as a sort of magic lantern, and projects

the image of the negative on to a screen that is fitted up in front of it. Focussing is done by means of the rack and screw of the camera, and the daylight outside the window can be rendered more even (if there are obstructions such as houses on the other side of the street, etc.) by placing a large piece of white cardboard at an angle of 45 degrees just outside the hole in the shutter, so as to reflect the light from the sky through the negative. When the image is sharply focussed on a piece of white paper fixed to the screen or easel (which should be quite firm and placed so that it is perfectly parallel vertically and horizontally with the camera body) the lens can be covered with a cap made with a piece of orange coloured glass in the top. This will allow the image to be still seen but will not fog the bromide paper, which is then pinned on the easel in the place occupied by the white paper. The exposure is then made by uncapping the lens, and after exposure the enlargement is developed in the manner described under **Bromide Paper**. Enlarging cameras are also sold for daylight enlarging. These consist of what is practically a small camera and a large camera front to front on a long baseboard. The negative is placed in a holder at the back of the small camera and focussed on the ground glass screen of the large camera, the image being projected by means of a lens fitted in the middle at the junction of the two cameras. The bromide paper in this case is fixed (in the dark room) in a large dark slide which is placed at the end of the big camera, and the smaller end is then pointed towards the sky or other even source of illumination. The dark slide containing the paper is opened and the lens in the middle is uncapped by means of a small shutter worked from the side.

Artificial light enlarging is usually done by means of an enlarging lantern which is practically the same in principle as the magic lantern. It is made of metal or wood lined with metal, and contains the illuminant, which may be either oil, gas, electric light or lime-light. A condenser (see) is placed in front of this, then the carrier for the negative and the lens for projecting the image on to the screen or easel. By alteration of the distances between lens to negative and lens to easel, enlargements of different sizes can be made. The greater the enlargement the nearer the lens will be to the negative and the further away from the easel, and *vice versa*. The exposure in making enlargements is best ascertained by means of trial strips of paper giving varying times doubling the exposure each time until the best result is obtained. This will serve as a permanent guide for future work. It is impossible to give an exact guide as so much depends upon the strength of light, density of negative and size of enlargement. It will be useful, however, to bear in mind that the exposure increases in ratio with the square of the enlargement. Thus, if an exposure of four minutes is required for an enlargement of two diameters (i.e., four times the area of the original negative), an exposure of sixteen minutes will be required for an enlargement of four diameters (i.e., sixteen times the area of the original negative).

Enlarged Negatives are made in the same manner as bromide enlargements except that the extra thickness of the glass plates must be borne in mind when focussing, also that the plates are much faster than the paper. Enlarged negatives are, of course, made from positives, which may be made by contact printing with the original negatives. Enlarged negatives may also be made on the bromide paper which is subsequently waxed or oiled to remove the grain of the paper when printing, or on negative paper which is specially made for the purpose.

EurySCOPE. A trade name for a double- or rapid rectilinear lens of large aperture.

Exposure is the generally accepted term for the period of time during which the light acts on the sensitive surface of the plate or film in the camera while a photograph is being taken. Exposure varies according to the following factors, all of which have to be taken into account if a good negative of any subject is to be secured—

(1) Actinic quality of the light. This depends on

time of day, time of year, and position of the object photographed.

(2) Speed of plate or film.

(3) Aperture or "stop" of lens.

(4) Colour and distance of the object photographed. It is obvious that shorter exposures are possible when the light is very bright than when it is dull, or later in the day, that a rapid plate needs a shorter exposure than a slow one, and a small stop in the lens will lengthen the exposure in the ratio described under **Diaphragms**. A dark subject will also need a longer exposure than a light one. A reliable table of exposures is given in the *Official Compendium section*, showing the alterations of light values for each month, and variations for different plate speeds and stops in the most simple form for immediate application. For local and general variations in light exposure meters are invaluable. Several excellent meters (no larger than a small watch) are on the market—notably, Watkins's meter and Wynne's meter. These also take into account all the other factors mentioned and are perfectly reliable for all problems of exposure.

Exposure Meter. (See **Exposure**.)

Factorial Development is the name applied by Mr. Alfred Watkins to that form of development which depends upon the time of the first appearance of the image in relation to the time of complete development. The "factor" is arrived at by dividing the time of total development with a certain developer (this is ascertained by trial) by the time of first appearance. Each developer has therefore a different "factor" and the application of this factor to the time of first appearance with any exposure will give the time when development will be finished. Factorial development renders the production of well developed negatives practically automatic provided the right factor of the developer is known and the exact time of first appearance of the image correctly noted. A list of factors for all developers is published.

Ferrotypes (the familiar tin-types of the seaside photographer) are positives taken by the wet collodion process on thin iron plate which is coated with brown or black varnish.

Ferrototype Plate. A specially prepared thin iron plate with a highly enamelled surface. Used in glazing paints. (See **Glazing**.)

Ferro-Prussiate. (See **Blue-Print**.)

Film-Pack. (See **Films**.)

Films offer many advantages over glass plates on the score of lightness and convenience in carrying. Their disadvantages are that they are not so rapid as the quickest plates and they do not keep so well. The flexible support which forms the base of films is made of celluloid. This is coated with sensitive emulsion similar to that on glass dry-plates. All modern makes of films are what are termed "non-curling," i.e. they do not curl when placed in the developing solution and they dry comparatively flat. This is effected by a coating of thin colourless gelatine on the reverse side of the film to counteract the "pull" of the emulsion. Films are obtainable in three forms: (1) Roll-films ("spools" or "cartridges"). In this form the film is in a continuous band wound with a black paper backing round a wooden spool which fits a receptacle in the camera. The end of the film, with its black paper backing is passed across the back of and inside the camera on to another spool on the other side. Sufficient film is wound off for the picture to be taken on it, the exposed portion is then wound forward again and a new unexposed portion takes its place. In this way a dozen pictures can be taken on one length of film which is finally wound entirely on the second spool. It can be removed from the camera in bright daylight and replaced with a new spool or cartridge of unexposed film. (2) "Film packs," in which a dozen films cut to size are ingeniously assembled and clamped one after the other after exposure from the front to the back of the holder by pulling out paper tabs. (3) "Cut films," which are supplied in packets like plates and are loaded into dark slides or holders, and exposed in a similar manner to plates. The development of cut films and films from film-packs present no difficulty. They may

be treated separately and developed in a dish like plates, or in special tanks made for the purpose, or, what is perhaps best of all, they may be developed, a dozen or more at a time, in a large deep dish full of diluted developer. They should first be soaked in plain water (in the dark-room of course) until limp, and then passed into the developer, which may be any standard formula of pyro-soda, metol, hydroquinone, rocinol, amidol, or azol, etc., diluted with twice the normal quantity of water. Films require full exposure to give good negatives, and they must be thoroughly developed. The usual fault with amateur's negatives on films is under-exposure and under-development.

Roll-films are treated somewhat differently. They may be cut into short lengths and developed in a dish or developed in one piece by passing backwards and forwards through a dish of developer, holding one end in each hand and see-sawing up and down, or the best plan is to develop in one of the special developing tanks now on the market for the purpose. When developed, the films are fixed and washed in the same manner as plates and hung up to dry in a good current of air.

Filter Paper and Filtering. Filter paper is specially prepared unsized pure paper used for filtering chemical solutions. For use, the paper should be folded in half, and then across the middle again, opening out to form a cone. This is inserted in a glass funnel (which is placed in the neck of a bottle), and the solution poured in. Filtering can also be accomplished by placing a small wad of cotton-wool loosely into the neck of a glass funnel and pouring the liquid through.

F/8, F/11, F/16, etc. These symbols appearing on a lens mount indicate the stops or diaphragm apertures, and bear a relation to the exposure. (See **Diaphragm**.)

Final Support. (See **Carbon Printing**.)

Finder. (See **View Finder**.)

Fish Photography. (See **Nature Photography**.)

Fixed Focus. A term applied to a lens when working at a point beyond which objects are in sharp focus. This varies according to the focal length of the lens and its aperture. A short focus lens with fairly small stop may give everything in sharp focus beyond, say 12 or 14 feet, whereas a longer focus lens with a big aperture may not present all objects sharply on the focussing screen until they are 30 or 40 feet away. Everything beyond these distances would, of course, be also in focus, so if the lens is set for this distance, it will not require re-focussing for any objects beyond. Objects nearer to the camera would not be in focus.

Fixing is the chemical action which removes from the plate, film, or paper any sensitive salts unacted upon by light or by the developer, thus rendering the negative or print unalterable by the further action of light. It is then said to be fixed. Hypo-sulphite of soda—commonly called Hypo—is the chemical generally used for the purpose. The average strength of the fixing bath for plates is—

Hypo 4 ozs.

Water 1 pint

while for prints it may be a trifle weaker. When fixing both negatives and prints care should be taken for the process to be thorough, or stains and fading will result. Negatives should be fixed for at least 5 minutes after the final disappearance of the milky appearance of the film when viewed from the back. (See also **Fixed Fixing**.)

Flare and Flare Spot. An optical defect due sometimes to the bright edges of the stops producing internal reflections in a lens. It shows itself in the developed plate in the shape of a circular fog-patch.

Flash Light is one of the most useful forms of artificial lighting for portraiture at night, as it needs no costly apparatus and can be accomplished satisfactorily by any amateur. Flash light is produced by the rapid burning of magnesium, either alone or in conjunction with some other substance rich in oxygen, such as chlorate of potash. If burnt alone it may be fired in a reservoir lamp, in which case the magnesium powder is driven through a methylated spirit flame by air pressure with a ball and tube; if a mixture is used it must not be fired in an enclosed lamp or an explosion

may occur. As the mixtures are best—giving the brightest and quickest flash, a lamp may be dispensed with altogether (although there are several excellent ones on the market specially constructed for the purpose). The flash mixture may be fired on a tin tray or tile, and is ignited by the application of a lighted match or taper or by placing it on a train of touch-paper or gun-cotton. A reliable flash-light mixture is made as follows:—

Chlorate of potash 60 grains.

Magnesium powder 30 grains.

Sulphide of antimony 10 grains.

The ingredients should be dried and sifted *separately*, and then mixed carefully with a feather or spill of paper. Avoid friction with any hard substance, or the mixture may explode. The best position of the light for flash-light portraiture is fairly high at an angle of 45° with the sitter's head, and about on the same plane, or a little in front of the camera. Shield the lens from the light. Focussing can be done by means of a light held near the sitter's face. All lights in the room may be kept burning during the actual exposure, provided none are shining direct into the lens. The lens does not need to be capped, as the exposure is made by the flash itself. The smoke that arises after the flash can be quickly cleared by opening doors and windows to create draught. A bigger light or two placed apart may be used for a larger room or group. The quantities of flash powder necessary for correct exposure varies with the speed of the plate, stop, colour and distance of subject. As a guide, it will be found that with lens at F/8, rapid plate, sitter in light clothes at 5 feet from light, 12 grains will be sufficient, at 10 feet 30 grains, at 15 feet 70 grains, at 20 feet 100 grains.

Focal length, focus, or equivalent focus. The focal length of a lens is the distance from the ground glass (or focal plane) to a point in the lens when a very distant object is in sharp focus. This point is roughly, midway between the combinations, in a doublet or in the centre of the lens itself if a single lens. When the focal length of a lens has been correctly ascertained the exact apertures of the stops may be measured and their values determined, if they are not already marked. (See **Angle of View** and **Angle of Lens**.)

Focal plane shutter is the name given to the type of high-speed shutter that works directly in front of the plate, inside the camera, or at the focal plane. It is actuated by spring rollers and consists of an opaque blind that rapidly winds on one roller at the bottom of the shutter as it unwinds at the top. In the centre of the blind is an adjustable opening or slit—this can be made wide or narrow at will. The speed of the shutter and the exposure of the plate depend upon the tension of the spring rollers and the width of the slit in the blind. With a very narrow slit and a high tension it is possible to make the blind travel across the surface of the plate at a great speed, exposing on one portion for 1/1000 second only. The focal plane shutter is of high efficiency and speed for speed passes more light to the plate than any other type.

Focussing cloth, an opaque cloth used to exclude light when examining the image on the ground glass focussing screen of a stand camera. It is most conveniently made of black velvet or silk or mackintosh cloth. The last is perhaps best as the camera can be protected with it in wet weather.

Focussing Scale. This is the engraved scale of distances that is affixed to most hand cameras and other cameras in which the picture is not focussed on the ground-glass screen. Its function is to serve as a guide for the position of the camera front or lens in obtaining sharp focus. The scale is usually marked in distances of feet or yards, and when the pointer attached to the camera front or lens is opposite any marked distance, objects at that distance will be in sharp focus in the resulting photograph. To make a focussing scale for a camera, the best plan is to adopt a practical test. First fix the pointer securely on the side of the camera front or other movable portion to which the lens is attached; fit a focussing screen to the back of the camera and carefully focus a very distant object—e.g. a distant church spire. Now make a mark where the pointer comes and call this "Infinity."

This will be the point beyond which all objects will be in focus (the lens should be used for these trials at full aperture). Now carefully focus an object 30 yards away and make a second mark. Repeat the process for objects at 20 yards, 15 yards, 10 yards, 8 yards, 6 yards, 4 yards, 2 yards, and 1 yard. Regard these, for practical purposes, as paces. The marks made where the pointer indicates these distances can be permanently indented in the woodwork of the camera, or they can be engraved on a small strip of ivory that can be screwed to the camera's side exactly over the original marks. For future use it is only necessary to set the pointer to any distance at which the object may be from the camera, and there will be no necessity for any other focussing.

Focussing Screen, the ground glass at the back of the camera upon which the image formed by the lens is seen. The focussing screen, although fitted to most cameras, is not used much by the hand-camera worker and "snap-shooter," who prefers to rely upon the focussing scale or scale of distances engraved upon the base board or side of the camera. For the worker with a tripod camera the focussing screen is a necessity, and the sharpness and composition of the picture is seen upon it. Oiling the screen renders the grain less visible, and a substitute for a broken focussing screen can be improvised out of a wet handkerchief or sheet of thin paper, a fogged, developed, fixed and washed plate, or a piece of plain glass dabbed over with putty.

Fog is the commonest of all faults in negative making. It appears as a veil all over the plate, in dark patches here and there, or as streaks from one corner or another. All these may be due to accidental exposure to light other than through the lens, to faulty apparatus and light leakage at corners of dark slides, etc. When fog has occurred in the camera the edges of the plate protected by the rebates of the dark slide will remain clear. If fog occurs through faulty dark-room light the plate will be fogged all over. Chemical fog may also produce a similar effect all over the plate. This may occur by forcing the development or the presence of too much alkali in the developer.

Formalin, a 40 per cent. solution of formaldehyde in water. It possesses the property of hardening gelatine, and renders it insoluble. It is valuable in the prevention of frilling which sometimes occurs with plates and papers in hot weather. A little may be added to the fixing bath.

French Chalk, used for polishing glass or ferrotype plates when glazing prints. (See **Enamelling and Glazing**.)

Frilling. Negatives and prints are said to frill when the film leaves its support at the edges. Occurs most frequently in the case of albumen or alum or a little formalin in water will prevent the frilling spreading. A bath of methylated spirit applied to the negative or print after washing will reduce the frilling and cause the gelatine to contract to its original size. In this condition it can be carefully replaced in its original position, and when dry will show no marks. If plates show a tendency to frill and no alum or formalin is obtainable, a wax or tallow candle rubbed round the edges before development will keep the solutions from these parts altogether.

Gelatine, an animal substance obtained by boiling bones, hoofs, horns and other animal matter. Used in the production of photographic emulsions and for coating plates and papers for various photographic processes.

Gelatino-Chloride Emulsion Paper. (See "P.O.P.")

Glazing or Glossing prints. The production of a high glaze or gloss on photographs is accomplished by "burnishing" (q.v.), "enamelling" (q.v.), or, in the case of gelatine-surfaced prints (i.e. gelatino-chloride, P.O.P., bromide and gaslight papers, etc.), by squeezing the prints in a wet condition into optical contact with a perfectly clean piece of glass, or ferrotype plate. The glass should be thoroughly cleaned and washed to remove all trace of grease, etc., and then polished with a little French chalk well rubbed in. The wet print face downwards is brought into contact

with the glass plate under water, withdrawn and well squeegeed to remove all air bubbles between the surfaces. A piece of paper on the back of the print will protect it from abrasion. When quite dry, the print will peel off with a highly glazed surface.

Glycerine is obtained from oils and fats as a by-product in saponification. It is used as a preservative of pyro and is used as a physical restrainer in various developing processes.

Glycin. A clean-acting developer, somewhat slow in action, but well suited for stand or tank development (q.v.).

Gold Toning. (See **Toning and Chloride of Gold**.)

Gum-Bichromate. A printing process in which pigment mixed with gum arabic in water and a certain amount of bichromate of potassium. The mixture is spread on paper and when dry is exposed under a negative. The picture is then "developed" by soaking in water until the unexposed portions of the pigmented gum are sufficiently washed away. The exposed portions (i.e. the shadows and half-tones of the picture) are rendered insoluble by exposure to light and remain on the paper. A considerable amount of local manipulation and control can be effected with this process, as the image can be worked upon and reduced with a brush, and at the same time repeated coatings and printings will give any extra density to the shadows or other portions of the picture. Printings in different colours can also be resorted to.

The sensitive coating is made as follows:—

a. Clear white gum 4 ozs.
Water 6 ozs.

Soak till dissolved and squeeze the mucilage through fine muslin.

b. Bichromate of potash 1 oz.
Water 9 ozs.

Mix equal parts of a and b and then stir in as much water colour (the ordinary tube colour) as will give the required tint. The mixture is then spread evenly and thinly on paper with a broad flat camel-hair brush. The paper (which should be a pure paper of good quality, hand made for choice) should be damped first to stretch it, then pinned down to a board and the mixture applied at once. When dry expose under the negative in the ordinary way until the details of the image are just visible in the surface of the pigmented paper. Develop in cold water by careful washing or spraying. If over-exposed, warm water may be used. When development is complete soak the print in an alum bath, rinse and dry.

Gum-Platinum Prints are produced by printing in the gum-bichromate process upon a base formed by a lightly developed platinum print.

Halation is the spreading of the light when photographing a brightly-lit object surrounded by dark shadows, such as an open window photographed from the interior of a room. Halation also occurs when photographing landscapes with branches of trees, etc., against a brightly-lit sky. Here the encroachment of the strong light will sometimes cut out the thin lines of the branches altogether. The most ordinary occurrence of halation is in interior work when the windows will appear as if surrounded by a halo of light. It is caused by light reflected from the back of the plate. Backing the plate is a preventive of halation. (See **Backing**.)

Half-Plate, a photographic size, $6\frac{1}{2} \times 4\frac{1}{2}$. (See **Sizes**.)

H. and D. An abbreviation of "Hurter and Driffield," the names of two investigators in the subject of plate-speeds. These initials, accompanied by a number seen on a box of plates, indicate that the speed of the plates has been calculated according to the sensitometric scales of Hurter and Driffield, and are comparable one with another. Thus a plate marked "H and D 200," is twice as fast as one marked "H and D 100."

Hand camera. is the name usually applied to any camera that can be effectively used in the hand, and for which a tripod or other support is unnecessary. This fact alone points to the need of an instantaneous shutter, as it is difficult to give a "time" exposure

when merely holding the camera in the hands. Exposures of half a second can, however, be easily given by holding the breath during the release of the shutter. Any camera of the type usually associated with a stand or tripod can, if fitted with an instantaneous shutter, view finder, and focusing scale, be used quite well as a hand camera. The essentials of a good hand camera are portability, readiness for use, a reliable and silent shutter, rapid lens, quick and certain plate-changing arrangement (either changing box, magazine, or dark slides), a good view-finder, and unobtrusiveness in appearance. Hand cameras are of many types, e.g., box-form, folding, small folding pocket-cameras, focal plane folding, and reflex (q.v.). [Also see **Instantaneous Photography and Camera**.]

High-Lights. The brightest parts of a picture, which are represented by the greatest density or opacity in the negative, as the face in portraits, the sky, and other bright portions in a landscape.

Howard Farmer Reducer. (See **Reduction**.)

Hydrochloric Acid. A strong corrosive fuming acid used in dilute form as a clearing bath for platinum-types and in other photographic formulae. The yellow "spirits of salts" can be used for cleaning bottles and measures, etc.

Hydroquinone. known also as hydroknone, hydroquinone, and quinone, a useful developing agent giving negatives of clean black and white character. A good one-solution formula is:—

Hydroquinone	90 grs.
Sulphate of soda	2 ozs.
Carbonate of soda	2 ozs.
Water	10 ozs.

This keeps well, and for use is diluted with four times its volume of water. For over-exposure add a little 10 per cent. solution of bromide of potassium. For under-exposure dilute still further with water. Hydroquinone works best in combination with metol, unless great contrasts are required, for which purpose (especially when copying black and white subjects) it is specially suited. (See **Metol-Hydroquinone**.)

Hypo. an abbreviation of hyposulphite of soda. (See **Fixing**.)

Hypo Eliminator. The best hypo eliminator is water. Negatives and prints should if possible be well washed in at least twelve changes of clean water after fixing in the hypo bath, or placed in running water for an hour. Allowing the prints to soak in plain water will remove the hypo. To hasten the removal of hypo when time is short or when on tour various chemicals have been suggested such as potassium percarbonate. To use this effectively, rinse the plate after fixing, cover with clean water and add three to five grains of the potassium for every quarter-plate. As soon as the liquid ceases to effervesce remove and rinse in clean water for a few minutes. "Anthion" and "Hypo" are two good commercial hypo eliminators. (See **Washing**.)

Instantaneous or Snapshot Photography. is the term applied to that phase of camera work in which pictures of moving objects are taken in a fraction of a second by means of "instantaneous shutters." These are placed either on the front of the lens, between the components of the lens, behind it, or immediately in front of the plate. The first are called "before-lens" shutters and are usually of the roller-blind "time and instantaneous" type, the second are called "diaphragmatic shutters," and are usually of metal with thin blades that open in a slit in the centre of the lens, the third are called "behind-lens" shutters and are similar in construction to the first, and the last are called "focal-plane" shutters (q.v.). Success in instantaneous photography depends largely upon correct exposure at the right moment so as to catch the moving object in the right position on the plate. The variations in speed attained by different moving objects has first to be considered. An engine crossing the line of view at right angles at 30 miles an hour needs a much quicker exposure than when it approaches the photographer at an angle or nearly end on. Again, the distance necessary for a galloping horse does not depend on his rate of progression, but upon the rate of progression plus the rapid local movements of the legs. An appreciation of these

points is rapidly gained by experience, and allowance made when making the exposure.

The essentials to be considered when dealing with high-speed work with the camera are: (1) good light, (2) a rapid plate, (3) a reliable instantaneous shutter, (4) a lens working at a large aperture, (5) as full an exposure as is consistent with the movement of the subject, and finally (6) careful development in dilute developer. The rule for ascertaining the required exposure for any moving object is as follows: Divide the distance of the object from the camera (measured in inches) by the number of yards per hour at which the object is travelling multiplied by the focus of the lens. Thus, if an object is 100 feet from the camera and the focal length of the lens is 5 inches and the object is moving at 20 miles an hour, the formula is:—

$$\frac{20 \text{ (miles)} \times 6}{100 \text{ (feet)}} = \frac{1,200 \text{ (inches)}}{35,200 \text{ (yards)}} \times 6 = \frac{1,200}{211,200}$$

The following table will be found an approximate guide for snap-shot work, assuming the object to be about 50 feet distant:—

Street scenes with people walking slowly	1-20 sec.
The same but with people walking more rapidly	1-45 sec.
Cattle feeding, sheep, etc.	1-15 sec.
Children playing or people walking very quickly	1-100 to 1-150 sec.
Horse trotting	1-150 sec.
Cycling or man running	1-150 to 1-200 sec.
Horse galloping	1-200 to 1-500 sec.

If the object is nearer the camera the exposure must be shortened, if further away it may be lengthened.

The development of instantaneous exposures calls for careful treatment and the plates can generally be regarded as under-exposed. Dilute developer with additional alkali is recommended, and care should be taken to shield the plate from the dark-room light during the prolonged development. (See **Developers and Development and Hand Cameras**.)

Intensification is the means employed for increasing the deposit or printing density of a negative. The most generally used method is the application of a solution of mercuric chloride and a subsequent darkening. To intensify a negative it is essential that it has been thoroughly fixed and washed. The mercuric solution is made up as follows:—

Mercuric chloride	2 parts.
Hydrochloric acid	1 part.
Water	100 parts.

The image completely bleaches in this. When the negative is white right through to the back it is well washed and immersed in

Sodium sulphite	1 part.
Water	6 parts.

or in a hydroquinone developer or in Strong liquid ammonia 10 parts.

Water. In either of these the image is blackened and is much denser and darker than it was originally. There are several other methods of intensification, such as the use of uranium, lead or silver, but the above is most generally useful for all purposes.

Isochromatic. (See **Orthochromatic**.)

Japline. A special kind of platotype paper with a very fine surface. (See **Platotype**.)

Kallitype. A printing process in which iron and silver salts are used. To make the first size the paper, which may be any pure good paper, and coat with:—

Ferric oxalate	75 grains.
Hot water	1 oz.
Oxalic acid	5 to 10 grs.

Dissolve, filter, cool, and add Silver nitrate 30 grs.

Keep the solution in the dark. Expose the paper until image is just visible and details show in highlights, then develop with

Borax	44 grs.
Rodile salt	33 grs.
Water	1 oz.

Potass. bichromate solution (5 grs. per oz. of water) . . 45 to 60 mins.

This produces fine black tones. After development, immerse prints in a 10 per cent. solution of Rochelle salts, and then in a 1 per cent. solution of ammonia 880. Wash and dry.

Kinematograph. (See **Cinematograph**.)

Labels for bottles in the dark room are best made from stout white paper, on which the names of the contents of the bottles are plainly written in waterproof black ink. If the bottles contain developers, toners, or other made-up solutions, the formula should be written on the label also. The labels should be firmly stuck to the bottle with good paste, and then sized and varnished. The solutions should always be poured out of the bottle on the side opposite to the label. This will prevent the chemical, that may run down the side, staining the label.

Landscape Lens is the term sometimes applied to a "single" lens. It is used with a fairly small stop to give good definition, owing to its lack of correction, but gives a brilliant image.

Lantern. The lantern as used in photography may be either the (1) "optical" lantern (the modern equivalent and development of the "magic" lantern). (2) The enlarging lantern or enlarger (q.v.). Both are similar in general construction and principles, and consist essentially of a lantern body made of metal or wood lined with metal, an illuminant inside the lantern body, a condenser (q.v.) in front of the illuminant to collect and condense all the available light, a carrier or stage for holding the lantern slide, transparency or negative in position, an objective or projection lens in front. Adjustments are included for altering the relative positions of the light and lens, and the image (i.e., the lantern slide or negative) illuminated by the light coming through the condenser is projected by the front lens on to an easel or screen in front. The size of the image or picture thrown on to the screen depends upon the distance the screen is from the front lens. The further away it is the larger the picture will be, and *vice versa*. The alteration of the distance of the screen will necessitate adjustment of the distance of the light from the lens. The light is centred (i.e. made to give a clear white disc on the screen) by moving it up or down or to right or left, or nearer or further away from the condenser. A combination of these movements will ensure the correct position being attained at which the best light is given.

Lantern Slides are small positive transparencies on glass, usually $\frac{1}{2}$ by $\frac{3}{4}$ inches, and are made by contact or reduction from negatives. These little pictures are projected by means of an optical lantern on to a white sheet or screen and appear enlarged a great many times their original size. The preparation of lantern slides needs careful technical accuracy in view of their subsequent enormous enlargement. The slides are made on commercially prepared lantern plates. These plates are coated with a fine silver-chloride emulsion and are either "rapid," for black and white tones, or "slow" (gaslight) for warm tones. The former can be used for reduction from large negatives by means of a reducing camera as well as for contact; the latter are generally used for contact only. For contact printing the plates are exposed behind a negative in a printing frame the same as when making a bromide or gaslight print. Exposure varies according to the speed of the plate, density of the negative, and intensity of the light. Correct exposure is found by trial, but is about the same as for bromide or gaslight papers respectively (q.v.). After exposure the plates are developed in developers similar to those for bromide or gaslight papers, or other formulae may be used. Hydroquinone developer (q.v.), restrained with ammonium bromide, potassium bromide, and ammonium carbonate, will give a great range of tones from sepia to red according to the amount of over-exposure. Pyro developer also gives good brown tones. Full instructions will be found with each box of plates. Lantern slides, when developed, fixed, washed, and dried, are bound up in contact with a "cover-glass." This is a piece of thin clear glass, same size as the slide, and is bound to it by thin strips of gummed paper or linen stuck on all four sides, the edges holding the two together. A cut-out mask of black paper is held between the

two showing only the required portion of the picture. Two white spots are placed on the front of the slide at the two top corners. This enables the lanternist to tell which is the right way up when placing the slides in the lantern carrier in semi-darkness.

Latent Image. The invisible image impressed upon the silver salts in the emulsion on a dry plate or bromide paper, etc., and brought into visibility by means of a developer.

Lens. This is probably the most important part of the photographers' outfit, and enables the image to be formed on the sensitive dry plate in the camera. Photographic lenses are of various types, from the single or landscape lens to the more complex modern anastigmat (q.v.) and telephoto lens. The better the lens the more highly it has been corrected for aberrations. Lens aberrations indicate some departure from the ideal performance of the instrument, and may be "chromatic," "spherical," "distortion," "curvature of field," or "astigmatism," etc. (q.v.). (See also **Aperture**.) Great care should be taken of a good lens to preserve it from scratches, the highly-polished surfaces are easily abraded, and the quality of the lens then suffers. (See also **Supplementary Lens**.)

Light-Fog. (See **Fog**.)

Light Filters. These are of coloured glass or gelatine, and are employed to cut out or block certain rays of light when using colour-sensitive plates. Called also "colour-screens," "ortho," "iso-screens," and "ray-filters." (See **Orthochromatic photography**.) When used to filter the light from a dark-room lamp, they are usually termed "safe-lights" (q.v.).

Magazine Camera. A form of hand camera containing a magazine of plates (in metal sheaths) at the back. They are changed automatically by pressing a lever outside the camera.

Magnesium. (See **Flashlight**.)

Magnifier. (See **Supplementary Lens**.)

Masks and Discs. Masks are pieces of black paper the same size as a negative, with a square, round, oval, or oblong opening cut in its middle. Placed between the negative and sensitive paper when printing, the mask protects the covered parts from light action, and they remain white. A portrait can thus be masked out of a group. The piece cut out of the middle of the black paper is called a disc, and if placed on the portrait or other portion that has been printed through the mask, will permit the surrounding white paper to print to a suitable tint. Cut-out black paper masks are also used in lantern slides (q.v.). (See also **Combination Printing**.)

Matt Surface Paper. The term applied to printing papers that are not glossy surfaced, but are not absolutely rough in texture.

Matt Varnish. (See **Varnish**.)

Meniscus. A term applied to a lens that is concavo-convex in form.

Mercuric Chloride. (See **Intensification**.)

Methylated Spirit. Used in photography principally for the purpose of quickly drying negatives and prints. If these are placed in methylated spirit for five or ten minutes after leaving the washing water, and then set up in a current of air or in front of a fire, they will dry in a few minutes.

Metol. A quick-acting developer, highly suitable for instantaneous exposures, develops shadow detail without rendering high lights too dense. Produces negatives soft in quality; also suitable for bromide and gaslight papers and lantern slides. A good formula is:—

a. Metol	75 grains.
Sulphite of soda	14 oz.
Water	30 oz.
b. Carbonate of soda	14 oz.
Bromide of potash	8 grs.
Water	30 oz.

Use equal parts of each.

Metol-Hydroquinone, known also as **Metol-Quinol** or **M.Q.**, an ideal combination of developers for all rooms, by combining the detail giving qualities of metol with the density producing characteristics of hydroquinone. Suitable for negatives, lantern slides.

and bromide and gaslight papers. A reliable formula is—

a. Metol	40 grains.
Hydroquinone	50 "
Sulphite of soda	100 "
Bromide of potash	15 "
Water	20 ozs.
b. Carbonate of soda	1 oz.
Water	20 ozs.

Use equal parts of a and b mixed for normal exposure. For over-exposure decrease the proportion of b and add a few drops of 10 per cent. solution of bromide of potash. For under-exposure increase b and dilute with equal bulk of water.

Mountant. There are several forms of pastes and other adhesives suitable for mounting photographs, the best known being starch-paste. This is made by mixing one ounce of starch (in powder) with one ounce of water, forming a thick even cream. Add to it, constantly stirring, eight and a half ounces of *boiling* water in which twenty grains of alum and five drops of carbolic acid have been dissolved. A clear translucent jelly of strong adhesive qualities should be formed; if it is not, heat it in a pan until it clears. This will keep about a week. Ordinary flour can be similarly treated and makes a good paste (not translucent), perhaps the best both for sticking and keeping qualities is dextrine.

Take:—

Best white dextrine	1 lb.
Cold water sufficient to make smooth stiff paste.	
Add water	10 ozs.
Oil of wintergreen or cloves	2 dram.

Mix the dextrine and water together until quite clear of lumps, add the further quantity of water, then the oil, and then bring the whole mixture to the boil, when it should be like clear gum. Pour into pots, cover up, and in from twelve to twenty-four hours it will set to a hard white paste that can be spread easily on backs of prints, etc., with the finger or a brush.

Mounting and Mounts. Mounting is the operation of affixing photographs to suitable mounts by means of an adhesive. Prints mounted wet are apt to cockle and bend the mounts unless specially pressed and flattened when dry. With larger sizes this tendency to curl can be counteracted by pasting another piece of wet paper to the back of the mount. Mounting the print dry is generally best. It can be pasted all over the back and applied carefully to the correct position on the mount (marked with a fine-pointed pencil beforehand—a dot for each corner), or it can be mounted by applying the adhesive to one edge only. A strong dextrine mountant or fish glue is best for this purpose. Thick neutral-coloured "art" papers are largely used for mounts, and a series of two, three, or four of these, showing a thin line of tint one under another, can be built up into a very effective surround for the picture. This is termed multiple-mounting. (See also **Dry-mounting**).

M. Q. is an abbreviation for "Metol Quinol" or metal hydroquinone developer (q.v.).

Muriatic Acid. Another name for hydrochloric acid.

Nature Photography. The photography of animals, birds, fishes, insects, plants and geological subjects may be included under this heading. A camera with long extension and great rigidity is needed. A reflex camera is specially adapted for birds and animals. A lens of large aperture is necessary and a silent shutter is essential. Rapid plates (orthochromatic preferred) and a great store of patience are also required. Animals and birds may be stalked in their nature surroundings and the photographs thus secured after careful watching and waiting are more valuable from the natural history point of view than when the subjects are photographed in captivity. Fishes are generally photographed in glass tanks with back and front very close together—practically holding the fish in position. The longest possible exposure that the subject permits should be given in nature photography, to secure all detail.

Negative is the term applied to the glass plate or film on which picture appears, but with the lights and shadows reversed. A negative is produced either in the camera by direct action of light through the lens or

by printing in a frame from a positive. (See **Exposure and Development**.)

Negative Storing. Boxes with grooved interiors are sold specially for storing glass negatives. Film negatives may be stored in envelopes, and books of envelopes are supplied by dealers for the purpose. Glass negatives may also be stored in paper bags (obtainable from the photo-dealer) and kept in sets or series in boxes with all particulars written outside. Another convenient method of storing large quantities is to keep the negatives (in two, film to film) in their original plate boxes, marking the outside of each box with a distinctive catalogue number for easy reference to the contents. The boxes should be stored standing on edge and not flat.

Nitric Acid, called also "aqua fortis." A corrosive, fuming acid used as a preservative in pyro-developer.

Oil-printing. The oil-pigment printing process is the production of an picture in greasy ink (printers' or lithographic ink) on paper that has received a coating of gelatine, sensitised with potassium bichromate, and exposed to light under a negative. The action of the light renders the bichromated gelatine insoluble in proportion to the densities or gradations of the negative, the darkest shadows being most insoluble and the high lights (protected by the white parts of negative) remaining untouched. The exposed paper is soaked in plain water and washed. The gelatine absorbs water and swells in exact proportion to the gradations of the negative. The parts that hold most water will now repel the greasy ink when applied with a brush (with a dabbling action). The shadow portions (insoluble gelatine and not swollen with water) "take" the pigment, and the ink will adhere all over the image in correct amount according to the lightaction, and the picture is formed with all detail and gradation. The gelatinised paper (carbon transfer paper answers the purpose well, although special papers are made for the process) is sensitised by soaking in:—

Potassium bichromate	1 oz.
Water	20 ozs.

for one minute. Drain and dry in dark.

Or a spirit sensitizer composed of:—

Ammonium bichromate	10 grs.
Sodium carbonate	10 grs.
Water	4 ozs.

One part of this sensitizer with two parts of alcohol and applied with a Blanchard brush (q.v.).

Printing takes about one-sixth the time necessary for P.O.P. After printing wash in cold water for half an hour. The print can then be dried (soaking it again when required) or pigmented at once. Pigmenting is conducted by laying the print face upwards on a pad of wet blotting paper. Remove surface moisture with fluffless blotting paper or a damp rag. Spread some of the pigment (sold specially prepared for the process) on a piece of glass or a palette. Dab one of the specially made fish-hog-hair brushes on the pigment until evenly distributed. Then with a "dabbling action" apply it to the print. Apply only a little pigment at first, increasing it as the image grows. Continue to apply the pigment until the picture is complete. A "hopping" action of the brush will take the pigment off. A "pressing" action will make it adhere. Thinning the pigment with a little boiled-oil or megilp will make it take more readily everywhere. In the production of prints in this process and also in Bromoil (q.v.) control of local tones or gradations can be easily accomplished. High lights can be cleaned up, shadows can be strengthened, details can be subdued or removed entirely, and in skilful hands a good composition can be made from a negative that would not yield a passable print in any "straight" process.

Optical Contact. An expression used to indicate the cohesion of two surfaces with no air spaces between. When a print is squeegeed on to glass and all air-bubbles are pressed out, it is said to be in optical contact.

Optical Lantern. (See **Lantern**.)

Orthochromatic, or Isochromatic, means "colour correct." The term is applied to dry-plates that are more sensitive to yellow and green than the "ordinary" plates. As they are still very sensitive to

blue and ultra-violet, a yellow screen or light-filter must be used with them to cut these rays out. The "ortho" plate used in conjunction with a yellow screen will give a comparatively colour-correct rendering of a landscape with clouds, or any other natural scene. "Ortho" plates must be developed in a deep ruby light, as the ordinary dark-room light will generally prove too actinic for their extra sensitiveness to colour. In other respects the treatment for "ortho" plates is the same as for ordinary plates. The "orthochromatic" screens or light-filters are made of yellow glass, with optically worked surfaces, or stained gelatine film. The screen is used either in front of or behind the lens, and increases the exposure twice, five, or ten times, etc., according to the depth of colour.

Ortol. A developer for plates, films, and bromide and gaslight papers. It gives an image of good density and colour. A useful formula is:—

(a) Ortol	70 grains.
Potassium metabisulphite	35 grains.
Water	10 ozs.
(b) Carbonate of soda	1½ oz.
Sulphate of soda	1½ oz.
Water	10 ozs.

Use a 1 oz., 5 oz., water 10 oz.

Over-Exposure. When a plate has been exposed in the camera for a longer period than would be necessary to give a good negative with all gradations reproducing the original, it is said to be over-exposed. An over-exposed negative is flat and lacking in contrast, but with plenty of detail. It may be remedied sometimes by intensification (q.v.).

Ozobrome is a method of making carbon prints from bromide prints or enlargements without the action of light. One bromide print may be used to make several ozobromes if required. There are two methods of procedure. The first process consists in placing the bromide print or enlargement in a dish of plain cold water, then immerse a piece of "pigment plaster"—similar to carbon tissue—in the special pigments solution supplied for the process. When the pigment plaster is well saturated (about three minutes) take out and place for a few seconds in a bath of hydrochloric acid (10 per cent. solution) 1 oz., water 25 ozs. Drain and then bring into contact—face to face—with the bromide print soaking in the plain water. Withdraw them together from the water and squeeze on a hard surface. Leave for twenty minutes, then develop in warm water (100° to 110° F.). Strip off the plaster backing and the carbon image will develop like an ordinary carbon print, but with the bleached bromide print as a base. This bleached silver image can be entirely removed now by means of a hypo bath. Wash the print and dry.

The second process is similar to the first up to the squeezing of the pigment plaster to the bromide print. After remaining in contact for twenty minutes, place them in cold water and strip off the bleached bromide print. Then bring the pigment plaster into contact with a piece of carbon transfer paper which has been previously well soaked in water. Squeeze together, place under slight pressure for twenty minutes, and develop in hot water (205° to 210° F.) as for an ordinary carbon print (q.v.). The bromide print can be used over and over again for other ozobromes, or redeveloped and kept in its original condition.

Panchromatic applied to dry plates, means sensitive to all colours of the spectrum as distinguished from orthochromatic (q.v.).

Panoramia Camera. A specially constructed camera for taking panoramic views.

Paper Negatives are useful in making enlargements. They are on specially prepared, nearly grainless, thin paper, coated with dry-plate (slow) emulsion. Paper negatives are developed in the same manner as ordinary glass negatives or films. Thin bromide paper may be used for making negatives for enlargements, but is too slow for exposures in the camera. If the grain of the paper shows it may be obliterated and the paper rendered more translucent by rubbing in melted paraffin wax or vasoline.

Paper Mineral. A fine tracing paper, very translucent and used for affixing to the backs of negatives for working upon in pencil or crayon.

Para-amidophenol. (See Rodinal.)

Parts. (See Weights and Measures.)

Passé Partout. A form of finishing prints for exhibition by binding them by the edges to a piece of glass cut to the same size as the mount. An effective and economical form of framing. A backboard is used to prevent damage to the back of the print, and rings are fixed to the backboard to hang the picture up. The binding strips may be paper or coloured tape and are stuck on with gum, glue, or paste.

Paste. (See Mountant.)

Paste, Encoustic. (See Encastic Paste.)

Photo Aquatint. A term applied originally to a form of photogravure and then to the gum-bichrome process (q.v.).

Phosphata Paper. A printing paper with an emulsion of silver phosphate. It is used in gaslight both for manipulation, exposure, and development. Development is physical in character and prints can be produced with great rapidity.

Photo Meter. A meter for measuring the strength of light. (See Exposure Meter.)

Photo-micrography is the process of obtaining photographic enlargements of microscopic objects by the aid of the microscope used in conjunction with a camera.

Photo-telegraphy. A new application of photography by means of which photographs can be transmitted over long distances by electrical means. The telephone line is usually employed and experiments in "wireless" transmission of photographs have also proved successful.

Pigment Processes. The various printing processes used in photography in which a pigment is incorporated or otherwise used in conjunction with some colloid which is rendered sensitive to light by chemical action. (See Carbon, Gum Bichromate, Bromoil, Oil-Printing, Ozobrome, etc.)

Pinhole Photography. Taking photographs by means of a camera with a pinhole instead of a lens. The pinhole is made with a pin or needle in a piece of thin metal (thin sheet brass answers well). The edges of the hole must be clean and free from burr. No focussing is necessary as the image is always in focus and the size of the picture depends only on the camera extension. The exposure varies according to the size of the hole which depends on the diameter of the needle that made it. It is roughly thirty to one hundred times the ordinary exposure.

Pinholes are small transparent spots that occur in negatives, and may be due to dust settling on the plate while in the dark slide or during exposure. They are also sometimes due to minute air-bubbles in the developer. They can be stopped out with a little water colour paint applied with the fine point of a small sable brush.

Plate-sunk Mount. A term applied to a photographic mount with an indented centre—to which the print is mounted—an imitation of the plate-mark round an engraving.

Platino-Bromide. A name applied to a certain type of bromide paper with a surface approximately resembling a smooth platino type print, which is further imitated by the colour and tone of the print when developed. Called also Platino-matt.

Platinotype. A beautiful printing process in which iron and platinum salts are utilised. The pictures obtained are in pure platinum and are absolutely permanent. The paper as sold is of a yellowish colour on the coated side. This is exposed under a negative in a printing frame and exposed to daylight until all details are just visible in a brownish tint on the yellow ground. The image is developed by placing the print in a solution of potassium oxalate (1 in 6 approximately) or in developer specially prepared by the makers of the paper. This gives perfect black tones. A different paper is supplied for sepia tones and is developed in a hot bath of oxalate solution 10 parts, saturated solution oxalic acid 1 part. Used at 150° to 160° F.

After development the prints are cleared and fixed in several successive baths of hydrochloric acid 1 part, water 60 parts. Finally washed and dried. Platinum papers must be kept in a calcium tube to protect them from moisture in the air.

Platinum Toning. (See **Toning**.)

P. O. P. An abbreviation for Printing-Out-Paper. All photographic printing papers that print under a negative in daylight and give a fully visible image are termed printing-out-papers, in contradistinction to development papers, in which the image is invisible or only partly seen after exposure. By P. O. P. is generally understood the gelatino and collodio-chloride papers and self-toning paper. These papers are exposed under a negative in a printing-frame and examined from time to time in subdued light to note the progress of printing. Printing is conducted in full daylight, but not in direct sunlight, unless the negative is very dense. Printing is carried further (darker) than is required in the finished print. In self-toning papers the printing is carried further still. When printing is complete, the print is ready for toning, after which it is fixed in hypos 3 ozs., water 1 pint, washed thoroughly and dried. (See **Toning**; also **Glazing**, **Self-toning**.)

Portraiture by photography is probably the most popular form of camera work, and is the branch that attracts most amateurs—although its special application is confined largely to professionals. Successful pictorial portraiture is comparatively difficult. To achieve something more than a mere snapshot of a person severe to the camera is considered. The background and environment of the figure need careful consideration. These should always be as simple as possible, so as not to detract from the interest of the portrait. (See **Background**.) The lighting is important. This will make or mar the portrait. The pose should be as natural as possible, and the sitter should not stare at the camera or appear "camera-conscious." Dark shadows, caused by strong top or side light, or by the sitter being too close to the light, can be rectified by reflectors of white material placed on the shadow side, or by translucent muslin diffusers placed between the sitter and the light. The most effective form of lighting for general portraiture is a good top side light, not too near, but a little in front of the sitter. A high window facing north, or a sloping skylight answers well. This lighting with a reflector should serve for most portrait studies. Ordinary rooms with a fairly large window can also be used for home portraiture by blocking up the lower half of the window, and using the upper portion only with the assistance of a reflector to light the shadow side of the face. Do not put the figure too close to the window or the lighting will be too hard. Long-focus lenses of big aperture are best for portraiture. Short-focus lenses give distorted perspective, and small apertures increase the exposure too much. Home portraiture can also be accomplished by flashlight (q.v.). Rapid plates (preferably orthochromatic) should always be used for portraiture and the largest stop in the lens. A full exposure gives the best results, and the negatives should be developed with asoft-acting developer such as metol (q.v.), rodinal, or a well-diluted pyro-developer with an extra amount of alkali. (See also **Retouching**.)

Positive is the name applied to the print or transparency made by contact, reduction, or enlargement from a negative.

Potassium Bichromate, a chemical of considerable importance in photography. It is met with commercially in fine orange-red crystals. Dissolves in water, and when incorporated with certain colloids, such as gelatine, possesses the property of rendering them insoluble on exposure to light. Is used in photo-mechanical processes, and collotype, etc. (See **Carbon**, **Gum-bichromate** and **Oil-process**.)

Potassium Bromide, used principally as a restrainer in development, and in emulsion making. As a restrainer it keeps the image clear, and assists in building up contrast and preventing general fog in cases of over-exposure. It is most conveniently used as a ten per cent. solution in water, i.e., 20 ozs. of solution contains 1 oz. bromide. A few drops are added to the developer.

Potassium Cyanide, used in making the cyanide reducer for negatives. It is a deadly poison and should not be handled more than necessary.

Potassium Ferri-cyanide, or Red Prussiate of Potash. Used in the iron or "blue-print" process

(q.v.), also in bromoil and other formulae. Used in conjunction with hypo in making a useful reducer for negatives. (See **Reduction**, also **Toning**.)

Potassium Iodide, used in making emulsions with silver nitrate.

Potassium Metabisulphite, used as a preservative in pyro and other developers and preventing staining of the gelatine film. Used also in making a non-staining acid fixing bath (q.v.).

Potassium Per-carbonate. (See **Hypo Eliminator**.)

Printing is the process of making a positive from a negative so that a picture is obtained in which the gradations of light and shade are represented as seen in nature. The term is more usually applied to contact work in a printing frame rather than to making enlargements. (See **Carbon**, **Cloud Printing**, **Bromide**, **Gaslight paper**, **Bromoil**, **Oil-printing**, **Platinotype**, **P.O.P.**, etc.)

Printing Frame. A wooden frame made to hold the negative while making contact prints. The negative and printing paper (film to film) are held in the rebate of the frame by a flat wooden back which is hinged in the middle, so that one end can be lifted to inspect the progress of printing. The back is held securely in position by two cross springs which clip onto the sides of the frame.

Pyro. The abbreviated name of pyrogallol (sold as pyrogalllic acid), an extensively used developing agent. Gives negatives with a tendency to yellow colour according to the formula employed. Sold in light, white, feathery crystals, very soluble in water or in heavier crystals or "tablets." The earliest formula for a pyro-developer for dry plates was pyro-ammonia. This has been practically discarded now in favour of pyro-soda, of which the following is a good formula:—

Water	30 ozs.
Potassium metabisulphite	1 oz.
Potassium bromide	60 grains.
Pyro	1 oz.

Stock Solution: β .	
Sodium carbonate 2 ozs.
Sodium sulphite 3 ozs.
Water 10 ozs.

For use take β : 3 ozs. water to make 20 ozs.
or β : 5 ozs. water to make 20 ozs.
Use equal parts.

Increase the quantity of β for under-exposure and dilute with more water. For over-exposure increase the proportion of α and add 20 to 30 drops of a 10 per cent. solution of bromide of potash. Pyro used in conjunction with metol gives a very satisfactory developer. A favourite formula is:—

α . Metol	45 grains.
Potassium metabisulphite	120 grains.
Pyro	55 grains.
Potassium bromide	20 grains.
Water	20 ozs.
β . Sodium carbonate	3 ozs.
Water	20 ozs.

For use take equal parts of each.

(See also **Acetone** and **Beach's Developer**.)

Pyroxyline. The chemical name for gun-cotton. It is produced by the action of nitric and sulphuric acids on pure cotton wool. It dissolves in a mixture of alcohol and ether, and is then known as collodion. This is employed as the base for the silver salt in the wet-plate process and in the preparation of collodion emulsions. Gun-cotton is also used as a means of rapidly igniting flash-powders. (See **Flashlight**.)

Quarter-Plate. A photographic size, $4\frac{1}{2} \times 3\frac{1}{2}$ inches. (See **Sizes**.)

Quinol. Another name for **Hydroquinone** (q.v.). **Rembrandt Effect** is a term frequently applied to that type of portraiture in which the outline of the features in profile are strongly lighted, while the remainder of the face and the background are in comparative shadow.

Rodinal. A concentrated "tabloid" developer of great utility for films, plates, bromide and gaslight papers, and lantern slides.

Rapid Rectilinear. A doublet lens that has been corrected for distortion of line. Usually ab-

breviated to "R.R. lens." Called also a "symmetrical lens" or "rapid symmetrical." When the two components forming the lens are the same in construction, one component or one half of the lens can generally be used as a single lens of double the focal length of the complete lens. (See **Lens**.)

Reduction (in Size). In the production of lantern-slides (q.v.), or small prints from large negatives, it is necessary to use a reducing apparatus. It consists, in practice, of a camera which takes a photograph on a small scale of the original negative or picture. The adjustments should permit the original that is being copied to be evenly illuminated by transmitted (or reflected) light, and the reducing camera should be truly square and vertical with the plane of the original, otherwise distortion will occur. (See **Copying** and **Lantern Slides**.)

Reduction in Density in negatives is secured by means of a reducer. A useful formula is the ferricyanide-hypo reducer (called also "Howard Farmer's" Reducer, after its inventor). It is prepared by adding a small quantity of potassium ferricyanide (10 per cent. solution) to hypo 1 oz., water 5 ozs. The mixture should be of a light yellow colour and keeps acting for only a few minutes. Negatives can be placed in the reducer straight from the bath. If hypo predominates in the solution, reduction affects the high lights, but when the ferricyanide is in excess, the shadows are attacked first. As soon as the required reduction is complete, wash well and dry. Persulphate of ammonia is also a favourite reducer. Local reduction can be effected physically by rubbing the required part of the dry negative with a wad of cotton wool soaked with methylated spirit.

Reflex Camera. A form of camera, usually used as a hand camera, in which the image cast by the lens is reflected (by means of a mirror placed at an angle of 45 degrees inside the camera) to a focussing screen at the top of the instrument. This serves the purpose of a full-sized view-finder, and the image can be focussed up to the moment of exposure. The plate is in position in its usual place at the back of the camera, and at the desired moment the mirror is released. It springs up and shuts out the top focussing screen, and simultaneously a shutter exposes the plate. Reflex cameras are especially useful for instantaneous work that requires great precision of focus, and also for natural history photography, e.g. birds, etc.

Registration. Any photograph may be registered (copyrighted) at Stationers' Hall on payment of a fee of 1s. The necessary form is supplied on application.

Rembrol. A commercial one-solution concentrated developer for plates, films, papers, and lantern-slides. Needs the addition of water only.

Restrainder. A chemical added to a developing solution to restrain its action. Usually Potassium bromide in a 10 per cent. solution is used with developers for negative work.

Retouching is the process of spotting out defects in photographic negatives or prints. It is generally accomplished with a fine-pointed pencil—after the film has been prepared to "take" the black-lead—or with a fine sable brush and water-colour of the right tint (for prints). To prepare the surface of a negative for retouching, a little special varnish must be rubbed over the film to give it a "tooth." A formula for preparing this is:—

Powdered resin 60 grains.
Turpentine 2 ozs.

The retouching pencil must be of hard lead—H.H. or H.H.II.—and must be sharpened to a fine needle point (by rubbing on fine glass paper after using the knife). The pencil is used on the parts requiring retouching with a loose "dotted" sort of stroke, making a series of tiny commas, or with a very light and small circular action. The point of the pencil must not be pressed hard and the density must be built up gradually. Spots, freckles, lines, etc., on the face in a portrait, which appear as almost transparent places in the negative are readily filled up in this manner and the texture of the skin can be smoothed considerably. It is not wise to overdo the retouching or all character will be removed from the features. An occasional rough print may be taken to

see the progress of the retouching, and if unsatisfactory it can be entirely removed by wiping the film with a rag dipped in turpentine. The process can then be started *de novo*. The retouching desk on which the work is done is a sloping board with side struts to hold it in position. A rectangular hole is cut in the middle of the negative field (film upwards) over this hole in grooves. As the retouching has to be done by transmitting light, a mirror is placed below the negative to reflect light from a window or lamp up through the hole in the desk. A top screen of wood or cloth cuts out extraneous light while working.

Reversal is when those parts of the image which should appear dark in the negative come up light, and *vice versa*. It is due to the extreme action of light on the sensitive film and is also known as solarisation.

Reversed Negative is one in which the position of the picture is reversed as regards right and left. Reversed negatives are used for certain photo-mechanical work and in carbon printing in single transfer. They are made (1) in the camera direct by taking the picture through the glass side of the plate or by means of a prism, (2) by stripping and reversing the negative film itself, (3) by reproduction from other negatives.

Rising Front is a movable panel of wood fitted to the front of the camera and holding the lens, which can be moved up and down so as to exclude or include more or less of the foreground of a picture without shifting the camera.

Rodinal. A concentrated one-solution developer for plates, films, papers, lantern slides, &c., needs only the addition of water for use. Made from paramidophenol.

Roll Film. A popular form in which sensitive films are supplied for use in cameras. The films are in a long strip backed with black paper and wound on a spool. (See **Film**.)

Roller-Blind Shutter. A form of instantaneous shutter in which a continuous strip or blind of thin opaque material, containing a rectangular opening or slit in the middle, passes from a roller at the top of the shutter and rapidly winds on another spring roller at the bottom. During its passage from one roller to the other, the opening in the middle uncovers the lens to which the shutter is attached. (See **Instantaneous Photography**.)

The body of the shutter itself is in the form of a narrow shallow box with an opening right through its smallest dimension. The rollers are fitted inside the box at top and bottom, and the lens of the camera fits into the opening at one side, leaving the other side free. The principle of the roller-blind is also applied to the Focal Plane Shutter (q.v.).

Safe-edge. (See **Carbon**.)

Safe Lights. This term is applied generally to the media or coloured screens employed in dark-room lamps, and may vary according to the sensitiveness of the plates or papers used. For bromide papers a good yellow light (orange glass or two thicknesses of special yellow fabric—sold for the purpose) will suffice. For ordinary and rapid non-ortho plates, ruby and orange glass combined, or two thicknesses of yellow fabric and one of ruby fabric will be safe. For orthochromatic plates a very deep ruby light is necessary or one of the commercially prepared safe lights may for the purpose should be used. (See **Dark Room**.)

Short-Focus Lens. A lens of which the focal length is less than the length of the longest side of the plate for which it is used may be called a short-focus, or wide-angle lens so far as that particular size of plate is concerned. Generally, however, the term means a lens with a focal length less than five inches. Such lenses have greater depth of focus (or definition) than long-focals lenses.

Screen, Coloured. (See **Orthochromatic**.)

Screen, Lantern. The screen or sheet upon which the picture in the lantern-slide is projected by the optical lantern (q.v.). To get the most brilliant result the screen should be white with a little blue in it and should be opaque.

Self-Toning Papers are printing-out papers in which the amount of gold necessary for toning the image is incorporated in the emulsion itself. Prints on

self-toning paper only require fixing in a plain hypo bath to give a finished picture of a pleasing colour. Thorough washing is necessary after fixing.

Shutters, Instantaneous. Mechanical contrivances for exposing the sensitive plate or film in the camera to the action of light for the fraction of a second, and allowing the image formed by the lens to impinge on the surface of the plate during that period. (See **Instantaneous Photography** and **Roller-Blind Shutter**.)

Silhouette Photography is that form of portraiture in which the face or figure is shown in profile in solid black against a plain white background. The method of producing these effects is to pose the sitter in profile against a white sheet. Focus the camera carefully and then exclude all light that may illuminate the near side of the figure or sheet. The whole of the light must come through the sheet and may be daylight or flashlight. Use a slow plate and develop with a well-restrained developer to give great contrast and density.

Sizes, Photographic. The principal sizes of photographic plates and papers are $1\frac{1}{2} \times 2\frac{1}{2}$; $3\frac{1}{2} \times 4\frac{1}{2}$; 5×7 ; $5\frac{1}{2} \times 7\frac{1}{2}$ (lantern plate); $3\frac{1}{2} \times 4\frac{1}{2}$ (quarter plate); 5×7 ; $5\frac{1}{2} \times 7\frac{1}{2}$ (postcard); $6\frac{1}{2} \times 8\frac{1}{2}$ (half plate); $6\frac{1}{2} \times 9\frac{1}{2}$ (stereoscopic); $7\frac{1}{2} \times 9\frac{1}{2}$ (whole plate); 10×8 , 12×10 ; 12×12 . The principal sizes of continental plates are $6\frac{1}{2} \times 9$ centimetres; 9×12 cm.; 12×16 cm.; 12×18 cm.; 18×24 cm.; 12×20 cm.

Skidagraphy, an early name applied to Radiography (*q.v.*)

Snap-shot photography. (See **Instantaneous Photography** and **Hand Camera**.)

Sodium Carbonate: ordinary washing soda. It is best to use the pure carbonate of soda prepared for photographic purposes instead of the common variety. Should be in clear crystals.

Sodium Hyposulphite. (See **Hypo**.)

Sodium Sulphate. Used largely in photographic formulae as a preservative for various developing agents, such as pyro, metol, hydroquinone, amidol, &c. It also prevents staining the film during development. Should be obtained in clear crystals. When it turns white or gets partly white it has oxidised and become sulphate and is then of no use for its original purpose.

Solarization. (See **Reversal**.)

Spherical Aberration is a defect in a lens and consists in bringing the rays passed by the centre of the lens to a focus at a point nearer than where the rays passed through the margins. Occurs most commonly with "single" lenses.

Spool. The name given to the rolled-up length of sensitive film backed with black paper and wound on a wooden spindle, used in a roll-film camera. A "spool" of film may contain sufficient for two, six, or twelve exposures, and is sometimes called a film-cartridge, and can be loaded into the camera without the need of a dark-room. (See **Film**.)

Squeegee. A useful accessory employed for squeezing a print into optical contact with a sheet of glass, or for expelling the air from between two pieces of paper (as in the carbon process) or other surfaces. It is made in two forms: the roller-squeegee, a tube of seamless rubber on a wooden spindle revolving in a convenient handle, or a flat straight-edged strip of rubber cemented or otherwise held in a long wooden holder. The latter form is more satisfactory in practice. When squeegeeing, start pressing out the air from centre of print towards the margins. Place a sheet of clean blotting-paper and then a sheet or two of ordinary paper over the back of the print to prevent abrasion.

Stains on Negatives. (See **Clearing Bath** and **Thiocarbamide**.)

Stand Development. This term is applied to the system of slow development in dilute developer, in which a number of plates are dealt with simultaneously. A grooved porcelain or metal tank is employed to hold the plates vertically, and almost any non-staining developer, such as metol, hydroquinone, adurol, redial, &c., may be used in a considerably diluted state. Development is allowed to proceed slowly (for many hours if the developer is very dilute), and this treatment generally tends to balance faults of exposure

and make the most of each negative. A developer specially suited for stand-development on account of its clean working properties is glycine. The following formula is suitable:—

Glycine	1 oz.
Sodium carbonate	2½ ozs.
Potassium carbonate	5 ozs.
Water	90 ozs.

Dilute one part of this with 6 to 12 parts water.

(See also **Tank Development**.)

Starch Paste. (See **Mountant**.)

Stenopic Photography. Synonymous with **Pinhole Photography** (*q.v.*)

Stereoscopic Photography is that form of camera work in which two photographs are taken simultaneously (if the subject is moving) with the same exposure, and with a camera having two similar lenses placed approximately the same distance apart as the human eyes. The resulting prints from the two negatives (usually taken side by side on one plate) when mounted, and viewed in a stereoscope, give the illusion of solidity to the objects photographed. This is due to the two points of view in the two halves of the pair of pictures. Two separate cameras may be used, or two exposures given with one camera—moving it a few inches to right or left before making the second exposure. Special stereoscopic cameras are sold for the purpose. When mounting the prints from a stereoscopic negative, care must be taken to mount the right hand print on the left and *vice versa*, as it must be remembered the negative has reversed the two views. The pictures may also be seen to advantage as transparencies.

Stock-Solution is the term applied to a concentrated form of any formula of which a portion is taken from time to time and diluted for use.

Stops. (See **Diaphragm**.)

Stripping Negatives. The film of a negative can be stripped from the original glass or collodion base by treating with the following solution:—

A. Methylated spirit	2 ozs.
Water	2 ozs.
Formalin	1½ ozs.

Take 8 parts of this solution and add 1 part hydrofluoric acid. Place negative in this first cutting film all round about ¼ inch from edge. The film readily loosens in this and can be taken off. It can then be transferred to a new piece of glass. (See **Cracked Negatives**.)

Sulphide Toning. (See **Toning**.)

Sulphite of Soda. (See **Sodium Sulphite**.)

Sunning Down is the term used when the high lights (e.g. the sky) of a print are perfectly blank and are coloured or tinted slightly by extra exposure to the light. In the case of printing-out-paper, this is effected by merely exposing the print to sunlight for a few seconds, carefully shielding the portions of the picture that are already sufficiently printed. A graduated sky effect, dark at the top and lighter near the horizon, can be obtained by slowly uncovering the sky part during the period of exposure to the light.

Swing Back. The movable back of the camera that can be swung vertically so as to get the plate truly perpendicular when the camera is pointed up or down.

Swing Front. The front of the camera holding the lens can in many cameras be swung from the centre so that the lens points up or down at will. Both the swing front and the swing back are useful movements for architectural photography.

Sulphuric Acid. A strong, corrosive acid used in the Bromoil process (*q.v.*). Develops great heat when diluted with water. Always add the acid to the water, and not *vice versa*.

Sulphocyanide of Ammonium. A very deliquescent chemical. Used in the gold toning bath. (See **Toning**.)

Supplementary Lenses, or magnifiers, are single lenses applied to the front of the ordinary lens for the purpose of increasing or decreasing its focal length. By careful calculation of the amount of this increase or decrease, objects at different distances can be brought into focus without altering the position of the original lens on the camera. These lenses are largely used in hand cameras that are not provided

with focussing adjustments. To find the focal length of a supplementary lens necessary to reduce or increase the focal length of a given lens, multiply the focal length to be altered by the focal length desired, and divide the product by the original focal length less the final focal length. A "positive" lens will reduce the focal length. A "negative" lens must be used to increase the focal length.

Symmetrical Lens. (See **Rapid Rectilinear**.)

Tank Development. This term is applied to the development of plates or films in a grooved metal tank or box. The plates (a dozen or more) can be treated at once according to the number of grooves) are held vertically in the tank and a clean acting developer of known strength poured on. The constitution of the developer may be so arranged that the development is complete in a certain time, say five, ten, or twenty minutes. This is arrived at by trial with a correctly exposed plate. A great number of developing tanks are now made and are obtainable from photographic dealers. They all embody the same principle, and many are made so that the plates can be reversed top to bottom at intervals during development. This prevents uneven development. (See also **Stand Development**.)

Telephotography is that branch of camera work in which a telephoto lens is used. The effect of this lens is to bring distant objects into focus, on the plate on a large scale, but without a long camera extension. The telephoto lens consists of a combination of an ordinary large-aperture photographic lens with a "negative" (or double concave) lens. This negative lens acts as a magnifier and the size of the image varies with the distance of the separation between it and the positive lens. To obtain the same sized rendering of distant objects with ordinary lens would require a camera of many times the length.

Temporary Support. (See **Carbon Printing**.)

Ten per Cent Solution. (See **Weights and Measures**.)

Thiocarbamide. A chemical used for making a clearing solution for negatives and for the removal of stains. The following is a useful formula:

Thiocarbamide 20 grs.
Citric acid 10 grs.
Water 2 ozs.

Thiocarbamide used in the developer will bring about reversal. (See also **Clearing**.)

T. and I. An abbreviation for "Time and Instantaneous," applied to photographic shutters that are capable of giving "time" exposures as well as "instantaneous."

Three-Colour Photography. (See **Colour Photography**.)

Tissue. (See **Carbon**.)

Time Development. A system of developing negatives in which the time of first appearance of the image bears a definite relation to the total time taken to develop the image fully. (See **Factorial Development**.)

Time Exposure is the term generally applied to an exposure given by uncapping the lens of the camera for any time more than a second. Less than one second's exposure is usually regarded as "instantaneous." When using an exposing shutter on the lens, exposures of from half a second to three or four seconds are sometimes referred to as "bulb" exposures (*q.v.*).

Toning is the process whereby the tone or colour of a photographic print is altered or changed by chemical means. Nearly every form of print is capable of being toned, but gelatino-chloride, or collodion-chloride papers (P.O.F.) and "bromide" or "gaslight" papers are most frequently treated in a toning bath. A favourite toning bath for gelatine P. O. F. is

Ammonia sulphocyanide 20 grs.
Chloride of gold 2 grs.
Water 20 ozs.

Dissolve the sulphocyanide in half the water and gold in remainder. Add gold to sulphocyanide, a little at a time, until all is mixed. The prints should be well washed in plain water first, and then placed in above bath until

all warm colour has disappeared from all but the darkest shadows when the print is viewed by transmitted light. Rinse the prints (a dozen or more) can be dealt with at once in the toning bath, and place in the fixing bath composed of:—

Hypo 3 ozs.
Water 20 ozs.

Fixation is complete in about ten minutes. Then wash prints for two hours, and dry. It is generally well to undertone, as the prints become much colder in colour when dry. A toning bath for giving fine brown tones is:—

Phosphate of soda 60 grs.
Chloride of gold 2 grs.
Water 40 ozs.

Brown and brown-black tones are obtained, especially on matt-surfaced P.O.F., by platinum toning. Use the following bath:

Potassium chloroplatinate 3 grs.
Sodium chloride (salt) 50 grs.
Citric acid 50 grs.
Water 20 ozs.

Immerse dry prints in 10 per cent. salt bath for five minutes, wash and tone in above. P.O.P. prints can also be toned and fixed in one operation (see **Combined Bath**). Browne and gaslight prints—usually black and white in colour—can be toned to almost any hue, from red to brown or blue. The best method of getting a rich brown or sepia colour is to bleach the prints in:

Potassium ferricyanide 40 grs.
Potassium bromide 60 grs.
Water 10 ozs.

When the image has quite disappeared, rinse and place in:

Pure sodium sulphide 40 grs.
Water 10 ozs.,

until the image reappears in a strong brown tone. Then wash well and dry. Red and blue tones are obtained, or bromide and gaslight prints by using the following solutions:—

a. Neutral potassium citrate 4 ozs.
Water 40 ozs.
b. Potassium ferricyanide 1 oz.
Water 10 ozs.
c. Copper sulphate 1 oz.
Water 10 ozs.
d. Uranium nitrate 50 grains.
Water 1 oz.
e. Ferric ammonium citrate 1 oz.
Water 10 ozs.

Fg. tones from warm black, through sepia to red use a, 5 ozs.; b, 2 ozs.; c, 1 oz., mixed and poured over the wet print.

For a different series of warm sepia to red-chalk colour use: b, 2 drams; d, 1 dram; glacial acetic acid, 2 drams; water, 10 ozs. After toning rinse in dilute acetic acid (1 in 100) and then wash in several changes of water.

Blue tones are obtained by immersing the prints in:—

Water 10 oz.
b. 1 oz.
c. 1 oz.
Nitric acid 1 dram.

Wash in several changes of water after toning and hang print up to dry. The methods of toning bromide and gaslight prints given above can also be used for lantern slides.

Transfer Paper. (See **Carbon**.)

Tripod is the name of the three-legged stand used for supporting the camera while the photograph is being focussed and taken. They vary in construction from heavy wooden affairs for bulky cameras to telescopic, aluminium, pocket tripods for small, light cameras. The best forms have adjustable, sliding leg joints, to permit ready levelling of the camera on uneven ground. The tripod top is the section to which the legs are attached and to which the camera is screwed.

Triple Extension means that the camera is capable of an extension of bellows three times the focal length of the lens ordinarily used.

Under-Exposure occurs when the amount of

light that reaches the plate or sensitive film through the lens is insufficient to record completely all details of the image—especially in the shadows. (See **Development**.)

Uranium. (See **Toning**.)

U.S. Numbers. (See **Diaphragm**.)

Varnish, Negative. Varnishes specially prepared for application to negatives and obtainable from all photographic dealers. The varnish is poured over the film side of the plate, which is then set up on end to dry in a warm place. A good cold varnish for application with a brush for glass negatives is:—

Celluloid 120 to 150 grs.

Amyl acetate 16 ozs.

A good varnish for films is:—

Dammar 50 grs.

Benzole 1 oz.

Matt varnish for applying to the back of a negative (gives a ground-glass effect and can be worked upon with a soft pencil) is made as follows:—

Sandarac 90 grs.

Mastic 20 grs.

Ether 2 ozs.

Dissolve and add

Benzole 1 oz.

Must be applied to the negative cold.

Vitrol, a commercial concentrated one-solution developer for films, plates, papers, and lantern slides, &c.

View Finder is the little instrument attached to most hand cameras for the purpose of determining the amount of subject or view that will be included on the plate at the moment the photograph is taken. The reflector form is, in effect, a tiny reflex camera, and the image formed by the small lens is reflected up by means of a mirror to the view point of the top of the finder. The direct vision-finder is usually a simple double-concave lens, rectangular in form, which presents the view in miniature when looked through. This type of finder affixed to the top of the camera with a sighting-pin arrangement permits the camera to be used at the eye-level and the object sighted as with a gun. Another form of direct-vision finder is made of a wire frame with intersecting wires crossing in the middle at right angles. This is fixed to the camera front (above the lens) and a sighting pin is placed at the back. This wire finder may be same size as the plate and the object is looked at through it.

Vignette and Vignetting. This is the method of softening off the edges of a picture until the margins are perfectly blank. It is generally used in portraiture and is accomplished by covering the negative with an opaque paper mask—fixed a little distance in front of the printing-frame, during printing. An opening is made in the mask approximating the outline of the portrait and tissue paper placed over the opening still further softens the effect. Vignetting, when making enlargements is accomplished by moving a piece of cardboard to and fro between the lens and bromide

paper. A hole being cut in the card to allow the required portion of the image to show through.

Washing Negatives and Prints is best accomplished in running water. The removal of hypo or other chemicals from the film cannot be done by allowing the plate or print simply to soak in water. Constant movement should be imparted to the washing water by means of a stream of water entering the washing trough (a large circular basin is good for prints) through a rubber pipe at an angle. Negatives should be washed vertically or film downwards, but not touching anything. Washing racks and tanks are now obtainable so cheaply that it is better not to risk the permanency of the negatives by not employing one to wash them thoroughly. The next best plan is to give the plates or prints a series of complete changes of clean water. Twelve changes with five minutes' soak between each will generally prove sufficient. (See **Hypo Eliminator**.)

Watkins. This name when applied to dry-plate speeds, e.g., "200 Watkins," signifies that the speed has been determined according to comparative tests calculated by Mr. Alfred Watkins. (See also **Exposure Meter and Exposure**.)

Weights and Measures. Photographic Formulæ are usually made up by apothecaries' weight:—

20 grains = 1 scruple.

3 scruples = 1 drachm = 60 grains.

8 drachms = 1 ounce = 480 grains.

Chemicals are usually sold by avoirdupois weight:—

437½ grains = 1 ounce.

16 ounces = 1 pound.

The fluid measure is:—

60 minims = 1 drachm.

8 drachms = 1 ounce.

20 ounces = 1 pint.

2 pints = 1 quart.

4 quarts = 1 gallon.

Whole Plate. A photographic size measuring 8½ by 6½ inches. (See **Sizes**.)

Wide-angle Lens. A lens is said to be wide-angled when its focal length is much shorter than the diagonal of the plate it covers. It embraces an angle of view that is comparatively wide. The same lens, however, used on a much smaller plate might be a mid-angle or narrow-angle lens. (See **Angle of Lens**.)

Wynne. The name of an actinometer, the calculations of which are sometimes used in giving the speeds of plates, e.g., "68 Wynne," means that the speed of the plate is 68 when used in conjunction with the Wynne meter. (See **Exposure Meter**.)

Xylonite. A form of celluloid, used in making light, unbreakable developing dishes. Spirit should not be used in these dishes or they will quickly get out of shape.

Yellow Screen. (See **Orthochromatic**.)

Yellow Stain. (See **Clearing Bath** and **Thiocarbamide**.)

PEARS'
of
DICTIONARY
MOTORING.

EDITED BY
H. WALTER STANER.
(Editor of "The Autocar").

Pears' Dictionary of Motoring

By H. WALTER STANER

(Editor of "The Autocar").

The rapid development of the motor in its various forms has brought into use so many words peculiar to the subject that an adequate Dictionary of motoring terms seems indispensable to motor users, the more so as automobile nomenclature is, unfortunately, at the present rather loosely applied in many ways. In an industry or sport covering such a wide range many new words are necessarily brought into play; some hitherto confined to other special branches are pressed into the service, while many ordinary every-day words are also commandeered and given a fresh significance in their new alliance.

In compiling such a glossary as this, therefore (which, naturally, should be as concise as efficiency will allow), it is a nice point where to draw the line—what words to include, what to omit—without being too diffuse on the one hand, too incomplete on the other. Consequently, it is necessary to have some foundation upon which to work, and for such a basis, in order to render this Dictionary as informative as possible, the reader has been assumed to have a fair equipment of general knowledge, but to be ignorant of motoring matters. This assumption, superfluous in many cases, must absolve the author from what, to the initiated, will seem a harping on the obvious, but even when apparently the commonest words are defined, it may be found, either that they have a peculiar shade of meaning in this connection, or that the definition includes some point of information which it is desirable to convey.

Absolute Pressure is pressure reckoned, not with the usual atmospheric pressure, but with complete vacuum as a basis. Atmospheric pressure is really 14.7 lb. per square inch above entire vacuum. Therefore, to obtain absolute pressures this amount has to be added on to the atmospheric pressure. The principle underlying the idea of absolute pressure is bound up with that of absolute temperature. The theory of absolute pressure is useful in calculating compressions in cylinders, etc., and a description of the method employed well illustrates its use. If we assume that a full cylinder contains air at atmospheric pressure—i.e., 14.7 lb. to the square inch—when this is compressed into half the space it will be at double the pressure (29.4 lb. per square inch); compress this again into half the space (in other words into a quarter of the original volume) and we get a pressure of 58.8 lb. and so on. This method, though not strictly accurate, is near enough to be used for practical purposes, and in any case it shows how absolute pressure is the basis of such calculations.

Absolute Temperature.—When a gas is heated it expands $\frac{1}{273}$ of its total volume for each degree (Centigrade) of heat by which its temperature is raised, or on the other hand, shrinks proportionately for each degree it is lowered; consequently, theoretically, any volume of gas at the temperature of zero, should shrink to nothingness at 273° below zero (Centigrade) or 459° (Fahrenheit).

Accelerator is a mechanism usually operated by a pedal to act on the throttle independently of the ordinary hand throttle lever. In the usual arrangement either the throttle hand lever or the accelerator can be used for operating the throttle, but the accel-

erator can only work above the minimum set by the throttle. Although the term "accelerator" is usually applied, "foot throttle" might more nearly describe this item.

Accessories.—This term is applied to the smaller and less important fittings that go to make up the equipment of the car, as for example, lamps, speedometer, etc., and may include essentials of the car, as for instance, coils, accumulator, magneto, and so forth. Accessories may be regarded as the smaller details, as distinct from the component parts. (See **Components**.)

Acetylene (C_2H_2).—A gas composed of 24 parts by weight of carbon to 2 of hydrogen: is derived from the action of water on carbide of calcium. In combustion it gives an extremely bright light, and as the carbide is exceedingly portable and the pressure of the gas can be made to regulate the supply of gas-making water, the system is very convenient for car lighting. Many acetylene lighting systems are automatically regulated by the pressure of the gas generated. Some regulation is necessary, since acetylene, when mixed with certain proportions of air, becomes explosive, and, in fact, has been used as a source of power in internal combustion engines. This same tendency also makes it subject to rather stringent rules by railway and transport companies when it is being carried in any quantity. (See **Lamps**.)

Accumulator.—Accumulators or secondary batteries are cells for the storage of electricity—they cannot generate electricity. They consist of lead and oxide of lead plates in a solution of sulphuric acid, the lead forming the negative pole, while the oxide forms the positive pole. For motor requirements they are

made in various sizes, usually to work at 4 volts, although 6 to 8 volt accumulators are sometimes used.

Adapter.—This term is usually applied in motor parlance to a fitting enabling one tyre pump connection to be used with tyre valves of varying screw threads. It is also sometimes applied to a type of electric fitting made to enable various types or sizes of lamps to be used with one socket.

Addendum.—The outer end part of a gear tooth beyond the pitch line; the part that meshes most deeply with the gear in engagement.

Adiabatic expansion of a gas takes place when no heat is being lost through any external source, all the heat that disappears going in actual work. When a gas is kept at a constant temperature and allowed to expand in a closed cylinder, its pressure, according to Boyle's law, varies inversely with its volume; that is to say, if a certain volume of gas at a given pressure is called on to fill twice the original space, its pressure sinks to one half, and so on. But the pressure of a gas also depends on its temperature; heat the gas and its pressure rises; cool a gas and its pressure decreases; also heat and work are mutually convertible. (See **Thermodynamics**.) If, therefore, in its expansion the gas gives out work, its temperature is lowered proportionately to the amount of work given out, and so the pressure falls more than proportionately to the increase of volume. When a gas, otherwise expanding according to Boyle's law, is doing a certain amount of work and so losing a certain amount of heat, the expansion is said to be adiabatic. Pure adiabatic expansion is more or less a theoretical expansion, because in practice a certain amount of heat is lost through the cylinder walls and other causes.

Adjustment.—The alteration of particular details to give varying results with a view to obtaining best results. The term is also used for the mechanism by which such alterations are effected.

Advance.—When the timing of the ignition is so altered that the spark in the cylinder passes at an earlier point in the cycle of operations, the spark is said to be "advanced." Roughly speaking, the most advanced point at which sparking takes place is when the piston is at a height of about half an inch before the top of its stroke. Advanced sparking is only intended for fast running, when the explosion only has time to begin to take real effect by the time the piston has reached the top of its stroke. (See **Spark Timing Variation**.)

Air Cooling.—See **Cooling System**.

Air Pump.—This term may refer to the tyre pump, to the pump for supplying pressure to force the petrol to the carburettor on cars with pressure feed, or to the pump of a self-starting device. In the second case the air pump may either be a hand pump used at starting (after which the exhaust gases from the engine supply the pressure) or it may be a small pump driven by the engine. Air pumps for self-starting apparatus are usually like very small motor bicycle engines, with the cycle of operations reversed (that is, with the crank shaft driving the piston instead of vice versa), and the pump cylinder is usually air-cooled and are driven off the engine, or sometimes from one of the gear box shafts.

Air Valve.—Besides being used for the tyre valve, this word describes the valve for admitting additional air to combine with the mixture from the carburettor on its way to the engine. In self-starting apparatus, too, the air at pressure used for starting is distributed to the proper cylinders in rotation by a valve which also may be called an air valve.

Alcohol.—An organic hydro-carbon compound (C_2H_5O) in liquid form capable of being used as a fuel in internal combustion engines. Though it can be used in ordinary petrol engines it gives the best results with very much higher compression pressures; in fact, 200 or 300 lbs. to the square inch is not too high for this purpose. Owing to the tax on alcohol in this country, however, its development as a fuel has not been practicable, although, since alcohol can be extracted from so many sources, its development offers very great possibilities for the British Empire. This tax is, of course, owing to the possibilities of its being used for drinking, and alcohol rendered undrinkable

and only intended for industrial uses is known as denatured alcohol.

Alignment.—When two shafts are placed with their ends opposed to each other in such a manner that the axis or line running all along the centre of one shaft continues in a straight line with the axial centre line of the other, they are said to be in alignment. Shafts may be out of alignment in two ways; either the centre line of one shaft may be parallel but not in line with another, or the centre line of one shaft may lie at an angle with that of another. Rigidly connected shafts running when out of alignment with each other cause excessive wear on their bearings, and may even break. Therefore, as the frame and mechanism of a car when travelling on the road can never be regarded as absolutely rigid, perfectly dead alignment cannot always be expected at all parts, and consequently flexible couplings are introduced to permit of unalignment without serious consequences.

Alloy.—A composite metal made up of a mixture of two or more other metals which are themselves chemical elements, or, in other words, incapable of being chemically split up into other constituents. Brass and gunmetal are, for example, typical alloys.

All-Weather Body.—Practically a light edition of the cabriolet, from which it may usually be distinguished in that the front corner pillars can be slid down when the hood is folded back, while in the cabriolet they remain standing. The windows, too, are generally merely detachable, or fold back, instead of letting down into the panels in the usual manner.

Alternating Current.—Electric current is generated in a dynamo by the work performed in cutting across with the armature the lines of force between the poles of the magnets. As the magnetic lines are cut first in one direction and then in the other by the armature windings, the current flows through the windings first in one direction then in the other. Where no provision is made to reverse every alternate flow of current, the current alternates in direction. Alternating current cannot be used for charging batteries without some means of transforming it into continuous current. The ordinary magneto generates an alternating current.

Aluminium.—A metal (Al chemically)—one of the chemical elements—which, as it is produced from the silicate of alumina in clay, is also one of the most plentiful. It is, however, not easy of extraction, hence its comparatively high price. For practical motor work it is always used in a more or less alloyed state, about 90 per cent. aluminium, and the rest copper and other ingredients. When properly alloyed it is extremely light for its strength (cast aluminium weighing 160 lb. and wrought 167 lb. to the cubic foot, specific gravities respectively 2.56 and 2.70), and can be easily cast at a fairly low temperature, although it takes a great quantity (not intensity) of heat to melt it. It is also much used in sheets for the making of motor carriage bodies. It is quite unsuited for withstanding great stress, and is not desirable for holding stress, but is tapped into it. It is also seriously affected by salt water, or even sea air, which corrodes it, and so, in general, is unsuited for marine work.

Ammeter.—An instrument for indicating amperage.

Amperage.—The current of electricity flowing in a circuit, or capable of being given out by a generator or accumulator. The amperage of an electrical circuit may be compared to the rate of flow of water through a pipe circuit.

Amperes.—The unit of electric current. It represents the rate of current flow necessary to overcome a resistance of one ohm at a pressure of one volt.

Angle Iron.—A form of manufactured wrought iron rolled in lengths so shaped in section that it forms the letter L, or two sides of a square.

Anneal.—To anneal metal practically means to soften it. In the case of steel this is done by heating it gently and then allowing it to cool as slowly as possible. Curiously enough, the method adopted for annealing copper is the same as that for hardening steel; that is to say, the copper is heated to red heat and then plunged in water. Annealed metal is generally less brittle and less liable to crack.

Antimony, a metal (chemical symbol for which is Sb), is an element, and is frequently found in small quantities in conjunction with tin, on which it has a hardening effect. It is sometimes used as a hardening agent in the manufacture of brass, bronzes and similar alloys. Its specific gravity is 6.7, weight per cub. ft. 418 lb.

A. O. V.—An abbreviation for "automatically opened valve." The term is usually applied to inlet valves so actuated.

Apron.—The under-shield of sheet metal that serves to protect the engine, gear-box, etc., from mud and road grit. In certain cars the apron is made integrally with the pressed steel frame.

Arbor.—Another name for a shaft, and one frequently employed in American practice.

Arc of Contact.—In a contact breaker or distributor for electrical ignition, the contact is often made by a piece of brass let into the face or circumference on the disc-shaped non-conducting body of the contact maker or distributor, and the part of the circumference over which this contact piece extends is called the arc of contact. It is usually measured in degrees, so as to express its dimensions in terms of the circle.

Armature.—Electricity is most economically produced by passing a piece of iron between the poles of a magnet, in which action work is done by the piece of iron cutting the magnetism between the poles. In a dynamo or magneto (which is really only a specialised dynamo) this piece of iron is elaborated into a system of coils of wire on a core, and is known as the armature. The greater the number of turns in the coils of wire in this case the higher the voltage of the current produced. This use of the word applied to a dynamo or magneto is its most usual application, but an armature may also be the bar of metal that is attracted across the poles of an ordinary magnet. In this form it is particularly familiar as the loose piece across the two ends of the ordinary horse-shoe magnet. The term also defines the soft piece of iron usually attached by a spring to the trembler of a high tension coil, so as to make contact with the core of the coil when the latter is magnetised.

Artillery Wheel.—The type of wooden-spoked wheel most generally employed for cars. It has wooden spokes and wooden felloes, and a metal (usually cast iron) nave or hub, into which the wooden spokes butt. **Asbestos** is a silicate of magnesia which can withstand great heat, and is much used for making joints, etc., that are subjected to high temperatures. It is placed on the market in the various forms of cord, rope, and sheets.

Atmospheric Pressure.—The envelope of air surrounding this earth is computed to be from 40 to 50 miles in height; that is to say, every square inch of surface on the earth has upon it the pressure of the weight of a column of air usually 40, or 50 miles high, but at very high points on the highest surface, of course, less. Normally it amounts to 14.7 lb. to the square inch. This explains the use of the term "an atmosphere," used sometimes as a unit of pressure. Such an "atmosphere" of course amounts to 14.7 gr. roughly speaking, 15 lb. to the square inch. Atmospheric pressure is usually taken as the starting point in discussing ordinary pressures, although for scientific calculations absolute pressure is very frequently used as a basis.

Atomiser.—A device for breaking liquid fuel up into minute particles, in order that the air may mix more completely with it so that a good explosive mixture is obtained. Owing to the requirements of paraffin when used in an internal combustion engine, atomisers are very frequently used in conjunction with that form of fuel. An atomiser must not be confused with a vaporiser.

Automatic.—A word used in automobile matters to denote the self-operation of an apparatus.

Automatic Valves are valves which, being fitted with springs, are capable of being opened by the suction of the engine; when that ceases they close or return upon their seatings by the action of the springs mentioned.

Auxiliary Air Valve.—At slow speeds an

engine requires relatively more air for carburation than at high speed. Accordingly in most carburetters the mixture is adjusted for low speeds, and as the speed rises auxiliary air is admitted above the carburettor jet, its admission being controlled by the speed of the engine, and consequently being proportionate to engine requirements.

Axial.—Along, or pertaining to, the axis.

Axis.—The longitudinal centre line of a shaft or other detail of construction.

Axle.—The shaft bearing the weight of a vehicle, and transmitting that weight to the hubs of the wheels. In motor cars the front axles, owing to steering requirements, are different in construction and principle from the back axles, and these latter again may be divided into two sorts, the solid axles upon which the wheels (usually driven by chains) revolve, and the live axles which usually form a casing in which is the mechanism through which each wheel is driven by a separate shaft. This mechanism is so arranged that the driving effort shall be exactly balanced to the requirements (see **Balance Gear**), so that when, in rounding a curve, the outer wheel has to traverse a greater distance than the inner, each wheel is given its correct proportionate amount of rotation.

Babbitt Metal.—The name given to a white metal used for lining bearings and composed of about 84 per cent. tin, 8 per cent. copper and 8 per cent. antimony.

Back Fire.—When from any cause an ignition occurs in the cylinder before the piston has reached the top of its stroke, and the engine is not running at sufficient speed to render the timing of such firing accurate, the crank shaft of the engine may momentarily tend to rotate in the opposite direction. This can happen either when starting the engine with the ignition advanced too far for the speed at which the crank can be turned round by hand, or when a short circuit causes the spark to pass at the wrong moment. In the first case the back fire may injure the person at the starting handle, in the other case it seriously stresses the engine and may cause a breakage, so causes of back firing should be carefully avoided.

The word is sometimes misapplied to an explosion in the silencer.

Back Pressure.—When a piston is on its exhaust stroke in the cylinder, it has to displace the burnt gases therein. Should the speed of the engine be excessively high or the openings from which the gases are expelled from the cylinder by the on-moving piston too small, the exhaust cannot then escape with sufficient rapidity and tends to retard the piston, and so act upon the engine as a brake. The pressure produced by these imprisoned gases is called back pressure.

Baffle.—A baffle plate is a plate to deflect the flow of fluids—generally gases. The general use of a baffle plate is found in a two-stroke engine for deflecting the entering charge upwards to the combustion chamber and so avoiding, as far as possible, its exit with the exhaust gases through the exhaust port, before the piston has covered over the latter.

Balance Gear is the more correct term for what is usually called the differential gear, mechanism which permits the driving wheels of a car to turn proportionately to requirements. Thus, when rounding a curve, the outer wheel of a car must travel a greater distance than the wheel on the inside curve, and while the balance gear permits this to occur, it yet obliges each wheel to perform its proportionate share of the drive, by very ingeniously balancing the resistance of the road wheels. In vehicles driven by side-chains, the balance gear is on the chain sprocket counter-shaft, but in live-axle cars it is nearly always contained within the back axle. Balance gears are either of what is known as "bevel" or "parallel pinion" type.

Balance Weight.—When the crank shaft of an engine rotates, especially at high speeds, the rapidly moving parts tend to cause vibration if their weight is not balanced. Accordingly the webs of the crank throws are sometimes extended on the side of the shaft opposite to the crank pin, and so formed as to constitute weights to balance this movement. Usually, however, in multi-cylindered engines the crank pins for adjacent cylinders are placed diametrically opposite each other (on the circle described by the crank.

pin) so that the weight of the one with its moving parts balances that of its neighbour. This practically gives correct balance in a plane transverse to the engine, but introduces a disturbing couple in the longitudinal plane, a point that has not, in the writer's opinion, yet received the attention it requires. As a general rule these balance weights on the rotating crank shaft may be about half the weight of the reciprocating parts. It is practically impossible to obtain perfect balance at all speeds, but this makes a very fair compromise.

Ball and Socket Joint.—When it is necessary to join two rods together so that the one shall be capable of moving in practically any direction from the other, a ball and socket joint is frequently employed. Its name describes it, the nearest analogy to it being the articulation of a thigh bone in its socket: in fact it is sometimes called an "articulate" joint. Good examples of the ball and socket principle may usually be seen in car steering connections which enable the connecting rods to move in any direction, rendered necessary by the movement of the car springs or the operation of the steering gear.

Ball Bearing.—There is obviously less friction when a cylindrical body, like a shaft, rolls over a surface than when it slides, but when a shaft is rotating in a plain bearing, its surface is only sliding relatively to the surface of the bearing. To obviate this sliding action and obtain rolling contact the shaft may be carried on steel balls which roll round on the outer ring fixed in the stationary housing. The principle is the same in roller or anti-friction bearings—that of transforming sliding contact into rolling contact.

Ball Cage.—The frame employed to retain the balls in a bearing apart from each other, for, as the front of one ball is naturally rotating in a direct direction from the back of its neighbour, contact of the two balls, if it were allowed, would entail an unnecessary amount of sliding contact and friction.

Ball Race.—The balls of a bearing being of hardened steel, roll around on the outer circumference of a hardened steel ring on the shaft and on the inner circumference of an outer ring of hardened steel placed in the housing. These are the outer and inner ball races respectively, and, generally speaking, to allow the bearing to adjust itself, it is advisable to leave one of these rings loose in its seating; whether it is the outer or inner race depends on circumstances.

Ball Thrust.—The ordinary ball bearing previously considered is taking the rolling load of a shaft, but in some bearings there is also a heavy end load, along the axis of the shaft. In ordinary bearings this is taken by collars on the shafts, running in grooves in the bearing, the end thrust being transmitted from the sides of the collars to the sides of the grooves against which they press. When the ball bearing principle is adapted to end thrust, balls are placed between the collars, the shaft and the bearing. The bearing surfaces rather the sides of the grooves in the bearing are substituted by hardened steel rings, held in the housing, so that the balls travel round along the faces of these rings. Generally speaking, a ball thrust is very much better than a plain thrust bearing.

Band Brake.—A band brake is a form of brake in which a drum (preferably of cast iron, owing to the greater frictional properties of that metal) is secured to the shaft which has to be braked, and the rotation of the drum is arrested by a steel strap passing around its outer circumference, and so arranged that, by means of levers, it can be contracted so as to grip the drum more or less tightly, and so arrest rotation. The strap is made of a strip of flexible steel, and the mechanism ought to be arranged so that the pull at one end of the strap is equalised by that at the other. Sometimes the band is provided with fibre pads which grip on to the drum surface instead of the steel. One or two modifications of this principle of brake are much used in testing engines for brake horse power (for which see **Brake Horse Power**) by registering the work absorbed by the brake at known speeds.

Bar.—This is a term commercially applied to those varieties of manufactured iron and steel made up in rods and bars. Steel or iron bars are made in many sections, among which round, square, rectangular,

flat rectangular, and channel section are the most usual. Bars are made by passing wrought iron or steel between the hardened rolls of powerful rolling mills, the rolls being formed with grooves arranged to afford a graduated series of shaping media, so that passing the red hot wrought metal first between one pair of grooves on the rolls, then another, and so on, finally reduces the material to the requisite section. In this process the metal is of course elongated, and so finally the resulting bars have to be cut off into requisite standard lengths.

Barrel.—Besides the more common use of the word barrel for both wooden and metal receptacles for holding liquids, the word is also used to denote the cylindrical front part of boilers of the locomotive type frequently found in steam waggon. This part of the boiler, as many readers probably know, is more or less filled with water through which pass tubes carrying the hot gases from the fire-box to the smoke-box before passing up the chimney.

Bath.—The word bath is sometimes used in motor parlance in connection with casings for transmission machinery (as for engines, chains, or gear wheels), which also serve as a receptacle for oil to enable the machinery to run in the lubricant.

Battery.—A battery is a collection of two or more cells capable of giving off electric currents. They may be regarded as of two sorts, primary, and secondary or storage batteries. For motor-car work the primary battery, when used at all, is nearly always found in its "dry" form. One form of dry battery is used for charging accumulators of a more portable nature, but for this purpose a type of cell capable of giving a constant voltage has to be used. A storage battery is the same as an accumulator, which see.

Beam.—The idea of a beam is so well-known that a definition is hardly necessary, but it should be pointed out that a beam may be supported at either one or both ends, and in engineering the term is not confined to girders or wooden joists, but embraces any structure or member subject to a load tending to cause bending stress; for instance the frames and the parts of the crank case that support the case of the engine constitute beams, so also does the frame of the chassis. It is immaterial whether the member is loaded for its whole length or at one point only, or whether the load is stationary or moving. Beams may take many shapes. For further particulars see **Bending Stress and Deflection**.

Bearing.—Besides the ball and roller bearings, described under their respective headings, there is the plain bearing. This is the rigid seating upon which a shaft rotates, and being stationary is naturally and practically invariably incorporated in the construction of the gearbox, engine, or whatever the detail to which it belongs. In a plain bearing the contact of the shaft against the bearing is pure sliding contact, and therefore it is necessary to render both shaft and bearing surfaces as smooth as possible. The surfaces must also be sufficiently large to withstand ample wear, and be of a suitable material for the shaft to run in. With shafts of steel the material usually employed is gun metal, and if the shaft be not hardened the bearing is generally lined with Babbitt or other suitable white metal, comparatively soft. For shafts of hardened and ground steel, gun metal by itself can be employed (it is in fact used with some soft steel shafts), while hardened and ground steel bearings or chilled cast iron bearings have also been used in conjunction with hardened steel shafts.

Beau de Rochas Cycle.—See "**Four-cycle Engine**."

Bell Crank Lever.—A bell crank lever is a device often used for transmitting a simple push or pull round a corner, so to speak. From the point at which the power is supplied, an arm runs to the fulcrum, and from the fulcrum another arm transmitting the movement projects at a suitable angle. Bell crank levers are considerably used in engine controlling devices.

Belt.—The simple and well-known means of transmitting power is made in various forms and of various materials. The best known—the flat belt—has not obtained much success for automobile work, and no flat belt cars are made to-day. For motor-cycle work,

also, it has not obtained, but in this branch a belt of "V" or wedged-shaped section has proved very successful. In the earliest days of the motor-cycle belts were made of raw hide twisted round ropewise so as to afford approximately a round section, but, except for the lightest machines, the round belt has been entirely superseded by the "V" sectioned variety, which should be made with its sides sloping at an angle of about 25° to the vertical. For a long time practically all belts for motor-cycle work were of leather, but the objection to this material is its tendency to stretch, and consequent need for constant adjustment. Accordingly, of late years, belts made of a mixture of canvas and rubber have been extensively used.

Bending Moment.—When a bending force comes into action on a beam, it acts at a certain distance from the support or supports of that beam, and, therefore, works with a leverage. For instance, a force of 200 lb. on the end of a beam 10 ft. long has exactly twice the effect than a force of 500 lb. on the end of a beam 1 ft. long. To obtain relative values for such influences, the term called the "bending moment" is used, the bending moment merely being the force causing bending, multiplied by the mean distance of that force from the support or supports of the beam upon which it is acting.

Bending Stress.—When a beam is loaded at a distance from its point of support (or supports), the load has a tendency to bend the beam, and the force which bends this beam is known as "bending stress." Bending stress is a compound of tension and compression. When applied to a beam, the beam tends to bend, and the lower fibres consequently to stretch while the upper fibres tend to shorten. In other words, the lower fibres are in tension, the upper in compression. Midway between there is a line all along the beam which is neither in tension nor compression; in fact, it is subjected to no stress at all. This is known as the "neutral axis," and the further the fibres are from the neutral axis the more pronounced is the stress, and the better position is the fibre in to resist such stress. This accounts for the shape of beams and girders which have their material cut away to a great extent all along the middle line, where it would be comparatively useless, and massed as far as possible at the upper and lower edges.

Bench Test.—See **Testing**.
Benzene or Benzol.—A by-product of gas manufacture, and at the present time is used to quite a considerable extent as a fuel for internal combustion engines. When used as a fuel it is most essential to ensure that the benzol becomes thoroughly mixed with the air. Its chemical composition is represented by C_6H_6 . Its property of dissolving indiarubber also renders it useful in tyre manufacture, repair, etc.

Bevel Gear.—The ordinary spur wheels with their teeth parallel with the axis are used for transmitting power between two shafts parallel to each other, but for transmitting power to shafts at an angle to each other bevel gearing is employed, especially between two shafts at right angles to each other. Bevel gear wheels have their outer or circumferential faces cut at an angle to the axis, the angle depending on the relative angle of the two shafts and on the ratio of the gearing. Good examples of bevel transmission between shafts at right angles to each other are seen in the back axles of many cars, though at present there is a tendency for worm transmission to supersede it, for though the bevel is perhaps slightly more efficient when new (it can reasonably show an efficiency of 85 per cent. to 90 per cent.), the worm transmission is the quieter in action.

Big End.—The lower part of the connecting rod where the bearings for the crank pin are accommodated.

Block Casting.—When all the cylinders of an engine are formed in one casting the result is said to be a block casting, or the cylinders are cast *en bloc*. With modern methods of casting this system has a good deal to recommend it notably lightness, compactness, and simplicity in machining. The system has, however, been somewhat abused by forming complete passages for the hot exhaust gases all along the casting. In any case, in designing block castings great care should be taken to allow for contraction and expansion when

working. Increased knowledge on the subject of engine balance and the possible adoption of a bearing between every crank throw may conceivably lessen the popularity of cylinders cast *en bloc*.

Block Chain.—Roughly speaking the ordinary chain for transmission purposes is a series of cross-bars, each connected to its neighbour by side links so that the teeth of the chain-wheel can work in between the side links, and thus the power can be transmitted between the cross-bars and the wheel teeth. In a block chain the cross-bars constitute the blocks, which are suitably shaped to engage with the teeth of the chain wheels and at the same time to connect with a pair of links at each end. The action between the block and the chain-wheel teeth is one of sliding. The block chain is, generally speaking, somewhat old-fashioned, having been superseded by the improved roller and inverted tooth types of chain.

Block Tyre.—A solid rubber tyre, in which the rubber tread, instead of being formed in a continuous band of rubber, is made up of a series of rubber pads or blocks secured to the wheel rim. In some cases, however, the tread is formed of blocks of hardened wood with the grain placed "end on" to the road surface.

Blowhole.—When the molten metal for a casting is poured into the mould, gases are given off both by the metal and by the mould under the action of heat, and in certain cases these gases may form bubbles in the metal which, when the metal has cooled, are not generally visible. These defects are called blowholes, and they may cause fracture of the casting.

Boiler.—A steam engine, of course, derives its power from the pressure of steam acting in its cylinders, and this steam is derived from water in a boiler. For road work there are several types of boiler. Broadly speaking, they may be classified into two groups—saturated steam boilers on the one hand and flash and semi-flash boilers on the other. The saturated steam boiler are the ones with which the public are most familiar, and they take several shapes, the locomotive type seen on tractors and many types of steam waggon being the best known. Then there are the vertical fire-tube types, in which a cylindrical vertical boiler contains the water, while the fire-box is at the bottom, and the gases from the fire-box are carried by vertical fire-tubes to the smoke-box at the top. Most boilers of steam waggon are on one or the other broad lines, but the water-tube boiler has also been occasionally and successfully used. In this the fire surrounds the water instead of *vice versa* as in the more ordinary types. In all these boilers a comparatively large volume of water is constantly being converted into a comparatively large volume of steam, which forms an ever-ready supply for the engine to draw upon. The flash and semi-flash boilers work on a totally different principle, and only generate sufficient steam for immediate needs. In fact, they may be said to live from hand to mouth. The engine operates a small pump which at each stroke injects into the boiler a spray of water just sufficient for the next stroke, and since the boiler is little more than a coil of tubing kept at practically red hot temperature this water is flashed into steam in an instant—hence the name. Of course the pressures employed under this flash system are very much higher than those with saturated steam, for not only does the boiler structure permit of higher pressures but the temperatures necessarily tend in the same direction. While the pressures in saturated steam boilers may go as high as 500 lb. to the sq. in., the pressure in flash boilers ranges anywhere from 500 lb. to 2,000 lb. to the sq. in.

Body.—This is a term used to describe the carriage portion of a motor car built for the accommodation of its passengers. Bodies are divided into various types—open or touring bodies, single and double landaulets, single and double limousines and cabriolets. The open, or touring-car body, is now generally of the torpedo pattern; that is to say, it has flush high sides with low wide seats, a scuttle dash-board fitted with a suitable screen and a Cape car hood which, with its side curtains, affords the passengers excellent protection in the worst of weather. Landaulets are bodies the

rear portion of which is made to open or close after the manner of a hood, leaving at times a permanent canopy over the driver's head; upon this luggage can be carried. This canopy is occasionally made to collapse with the hood of the body so as to give an open car when desired. Limousines are bodies entirely enclosed in rear of the driving seat, and affording accommodation for four or five passengers. When the latter is the case, they are described as double limousines. Roofs of these carriages are made suitable for the carriage of baggage. Of late years designs wholly enclosing the body space have been turned out, both for large and small cars, giving equal shelter and protection to the driver and occupants of the front seats as to those in the rear of the vehicle. Cabriolet bodies are the modification of the landaulettes, but with heads of cabriolet form. Two-seated bodies are made in great variety, but the generality of them take the single torpedo or cabriolet form, and at times are built on the wholly enclosed principle, when they are eminently suitable for medical and business men.

Bolt.—There are many types of bolts, the ordinary variety for engineering work having a hexagonal head. There is the cheese-headed bolt with a round, flat head; and as this head usually fits into a counter-sunk hole and entails the use of a screwdriver, the head is slotted across. Some bolts have cup-shaped heads like a rivet, and when used for wood work the shank is made square in section below the head to prevent turning round.

Bonnet.—The casing beneath which the engine is usually enclosed—we say "usually," because on some vehicles on which the engine is not placed in the front of the chassis, a dummy bonnet is occasionally provided. The bonnet is made of sheet metal, and is a sort of box, each side of which is hinged and can be lifted up to expose the engine for inspection or repair.

Boot.—The space at the back of a car body underneath the back seat, chiefly used for the storage of tools and car requisites.

Bore.—The lumen of an engine is the internal diameter of the cylinder. The word is also used as a verb to describe the process of machining the cylindrical inside of any details, as for example cylinders. Boring is akin to drilling on a large scale.

Brace.—A tool used for drilling when the tool has to be brought to the work rather than the work to the tool. It is usually provided with a ratchet mechanism, to rotate the drill. The same word is sometimes used to denote a stay holding, say, two parts of the frame together, or as a verb to the same effect.

Bracket.—In motor-car parlance the fittings for carrying the lamp are most generally called "brackets," but besides the lamp brackets there may be others in the shape of spring hanger brackets and so forth. The term is somewhat loosely used.

Brake.—A device for retarding a car by retarding the rotations of certain shafts. In practice brakes are usually applied either to the wheels or to the driving shaft of the gear box. In the former case they are usually of the internally expanding type covered in, and very like an expanding clutch. The other type of brake, exactly opposite in principle, is known as the external contracting type (see **Band Brake**).

Brake Block, equally frequently known as "Brake Shoe" is the part that is brought into action to press forcibly on the brake drum and so retard its rotation.

Brake Horse Power.—In an engine worked entirely without friction, the pressures in the cylinders would have their full effect (apart from their losses by cooling, etc.), but the friction on the several parts may absorb a good deal of the power, so that the amount actually given off at the engine shaft is materially less than that exerted in the engine cylinders. It is, therefore, the power at the engine shaft that is the practical measure of the capacity of an engine, and as this factor is usually measured by an instrument that is really a brake capable of measuring the work given off by the engine at any given speed, it is known as "Brake Horse Power."

Brake Shoe.—See **Brake Block**.

Brass.—Brass is an alloy composed, roughly speaking, of two parts of copper to one of zinc, although the proportions may be varied considerably. These alloys containing more than 80 per cent. of copper exhibit a reddish-yellow colour, while if the amount of copper falls below 30 per cent., the alloy is no longer yellow. Its average weight is 505 lb. per cub. ft., and specific gravity 8.10. Brass can be cast or rolled, but it is not a very strong metal, being preferably used for the more ornamental parts that are not subject to great stress. It must not be confounded with bronze or gun-metal. The word brass is also used frequently to designate the two halves of a plain bearing, since these parts used to be made of brass, though now usually of gun-metal.

Brazing.—Brazing means the process by which brass is melted, so as to act as a medium for joining one piece of metal to another. Its most usual application is for joining steel tubes to their lugs or sockets, and the process consists of heating with a blowpipe a certain amount of soft brass or "spelter" with flux (usually composed of powdered borax) until the brass melts and flows into the joints to be connected. The flux makes the molten brass flow into the joints, and when cool it adheres to both surfaces so strongly as to constitute a very strong joint. Care should be taken, however, in brazing to avoid overheating the metal. Considerable heat is required, but only just sufficient heat should be used.

Bridge.—Sometimes a port has to be divided into two or more openings to avoid piston rings, etc., to work past it without catching on its edges. The metal from either side is then turned across the port at materials, and the metal which thus divides the port is known as a bridge.

Bridge (or Bridge Piece) is a term sometimes used to designate the yoke pieces used for holding down the valve-chamber caps in certain designs of engine. It is also used largely to designate any clamping-down device in which the clamp is of bridge shape, and also for the piece that carries the contact screw with which the trembler on an ignition coil makes contact, since this bridge piece strides the trembler like a bridge.

Bronze.—Generally speaking, bronze is regarded as the same as gun-metal. It is an alloy of copper and tin, although for special purposes small quantities of lead or zinc are added. It is very widely used for bearings, a good mixture for this purpose being copper 80 per cent., tin 18 per cent., zinc 2 per cent. The word bronze is also applied to various mixtures of copper with other metals. The best known of these alloys is phosphor bronze, very widely used for bearings, while aluminium and manganese bronze are other compounds possessing considerably greater strength than the ordinary gun-metal—especially the manganese bronze. The weight of gun-metal varies slightly according to its composition, but 534 lb. to the cubic ft., and a specific gravity of 8.56, are fair averages.

Brush.—This term is usually applied to a device fitted to electrical machines, such as dynamos or generators, and employed for collecting the current from the rotating armature or commutator of the machine, and delivering it to the stationary wires which conduct the electricity where required. Such a brush is usually made of carbon and should bear as lightly as possible, but quite firmly, on the rotating part from which it collects the current.

Brush-Holder is the fitting for holding the brush in position.

Buckle.—This word is usually applied to the clip that binds the plates of laminated springs together, and at the same time attaches the springs to the axles. It is also used as a compound word (see **Turn-buckle**).

Bucket Seat.—A small round-backed seat for a single passenger. It is the style of seat usually fitted on racing cars, and is generally made of aluminium.

Bush or Bushing.—Is usually a gunmetal tubular bearing, but in many cases the word is applied to any form of liner in a hole of comparatively small size.

Butterfly Nuts.—See **Nut**.

Butterfly Throttle.—A form of throttle consisting of a circular plate pivoted across its centre, so

that when shut it blocks up the induction pipe, and, when open, lies along the axis of the pipe.

By-Pass.—When a fixed volume of fluid as, for example, fuel to an engine, is delivered positively and forcibly in a given time, the requirements might be adjusted by regulating valve, but if the amount delivered and the force with which it is delivered remain constant, and the valve were shut down, a breakage might result from the pent-up pressure of the fluid. To avoid such a result a by-pass is very useful. It is merely a tube or passage so arranged as to carry all superfluous fluid (over and above requirements) back to its source of supply.

Cabriolet.—A type of car body which can be entirely opened or entirely closed at will, the upper part consisting practically of a folding leather hood and the side windows or lights.

Cage.—The withdrawable seating surrounding a valve with its walls constitutes the "cage." The word is also applied to the frame for separating the rollers or balls of a bearing.

Calcium Carbide (CaC_2) is the material which, in combination with water, gives off acetylene gas.

Cam.—A cam is a projection on a rotating shaft, the duty of which is to move a lever or tappet as it comes into contact with the cam. The cam is the part of the shaft. Cams are most generally employed for operating engine valves, and are pieces of hardened steel (secured to or made in one with the shaft) having the profile of their circumference circular for part of the way round, the projection which lifts the valve rocker or tappet extending around the rest of the circumference. As the tappets are held against the circumference of the cam indirectly by spring pressure, sometimes, though rarely, a depression is formed on the cam circumference instead of a projection, in which case the movement of the valve is obtained by the spring being allowed to force the tappet into the depression, the valve being replaced as soon as the circular part of the cam comes to bear against the tappet. These are the two most usual varieties, but cams with sideways action are sometimes made having the projection or depression on the side. For operating engine valves the efficiency of the engine greatly depends on the profile of the cam projection, which has to be shaped so that the tappet or rocker passes easily from the curved part of the circumference on to the projection or depression and back again. Cams are also used for operating pumps, etc.

Camber is the amount of vertical curve or bend in such things as frames or car springs.

Camshaft.—The shaft to which cams are secured. In the ordinary four-cycle internal combustion engine the camshaft revolves once for every two revolutions of the main engine shaft, and is driven through spur, skew, or bevel gears—or even inverted tooth chain drive, to give the correct speed. As it runs at a slower speed than the engine shaft, the camshaft is often used to drive the magneto, water and oil pumps.

Canopy.—A canopy is a light roof supported on pillars, sometimes fitted on cars. It has been displaced in late years by the type car hood. Side curtains were usually used in conjunction with these canopies.

Capc Car Hood.—A light hood used on cars with open bodies and extending completely from back to front of the body. It is built up on two systems of hoop sticks, the one radiating from a centre towards the front, the other from the back. Of late, however, this type has been superseded by one that can be folded by one man. In this the front hoopsticks are supported on a lazytongs arrangement, the back hoopsticks only working from a pivoted centre. Capc car hoods are generally provided with side curtains, which can be brought into use or not, as required.

Carbide.—See Calcium Carbide.

Carbon.—The deposit found on the inside walls of cylinder combustion chambers. It is caused by the use of too much lubricating oil which, on working in the combustion space, gets burnt and is deposited in the form of carbon. The word carbon is also applied to the carbon brushes or carbon contacts in magnetos or other electrical details.

Carburetted Alcohol is alcohol in an exceed-

ingly fine state of division, and mixed with air in such proportions as to render the mixture explosive.

Carburettor.—Even the most inflammable of liquid fuels will not burn without air, but with air mixed in the right proportions they will burn so exceedingly rapidly that the burning constitutes an explosion. The more perfect the mixture the more forcible the explosion, and the carburettor is a device for mixing together the air and fuel before admission to the engine cylinders. The simplest form of carburettor—the surface carburettor—is designed to expose a sufficiently large surface of petrol to the air to enable the latter, on its way to the engine, to take up a sufficient amount of petrol vapour. Surface types of carburettors, however, have fallen into disuse, in favour of the float feed carburettor. In this petrol flows into a chamber containing a float, and when sufficient has entered to raise the float to a certain level, the float by rising moves a valve which cuts off further supply; consequently the petrol is retained at a constant level in the float chamber, whence it is sucked by the engine through a jet tube having a tiny spray hole. As it issues from the jet, the air, which the engine is also sucking in, mixes with the petrol, and, laden with petrol vapour, passes to the engine. As the suck on the petrol is proportionately less at low engine speeds or at starting, less air at starting or at slow speeds should be admitted, and these variable relative proportions of air and petrol are obtained in different ways. They may be arranged either by varying the petrol or the air supply. The petrol supply is frequently varied by having multiple jets which are brought, first one then another, into action according to engine requirements, while variable air supply is usually obtained by designing a carburettor to deliver a very strong mixture and adding additional air, which latter, as it is more or less proportioned to the engine speed and suction, is obtained through a nicely adjusted suction valve, or one operated by a diaphragm moved by the suction.

Carburation.—The charging of air with a proper proportion of petrol vapour to render the mixture efficiently explosive.

Cardan Joint.—See Universal Joint.

Cardan Shaft.—See Propeller Shaft.

Case Hardening.—Iron or mild steel, which are comparatively soft metals, may be case hardened when a hard surface is required. Since steel is, roughly speaking, only iron combined chemically with a certain amount of carbon, if the external surfaces of the piece to be treated can be made to combine with a certain additional amount of carbon, we shall have steel of a surface capable of being made sufficiently hard. Hardening is usually effected by heating the pieces to be treated in contact with horn, bone dust, or anything that can be converted in the process into animal charcoal. Prussiate of potash can also be used. The metal then combines the toughness of the softer metal with the hardness of iron and steel. The depth of the hardening is varied by the length of time allowed for heating, this varying from one or two to twenty-four hours. When taken out of the case hardening furnace the pieces should be allowed to cool to a suitable temperature—usually dull red heat—then plunged into water or oil.

Castellated Shaft.—A shaft formed with keys or feathers solid with the material of the shaft, so that any sleeve fitted on to it is bound to rotate with the shaft though it may be free to slide along it. Castellated shafts are most frequently employed in gear boxes, to enable the change speed gears to be slid into engagement along them.

Casting.—A casting is made from metal that has been melted, and run into a mould to obtain the correct shape. Castings are used where the shapes are too complicated for forging, as, for example, in the case of water jacketed cylinders. Castings can be made in many metals; aluminium, brass, gun-metal, iron and steel being those most usually employed in motor work.

Cast Iron is a variety of iron that can only be worked by melting, and is used for many details in construction, especially of such complicated shapes as cylinders, etc. It is somewhat brittle. Its specific gravity is 7.11 and a cubic foot weighs 445 lb.

Cast Steel.—See **Steel**.

Cell.—A single element of an electric battery.

Celluloid.—Often used for accumulator and other accessory details, is essentially compressed cellulose, cotton, and so is highly inflammable, though at the time of writing a non-inflammable celluloid has been announced. Celluloid accumulator cases, etc., may be patched with sheet celluloid treated with amyl-acetate.

Centrifugal Pump is one which forces liquid as required by the centrifugal action of vanes secured to a shaft and whirling round in a casing containing the liquid. This whirling action tends to throw the liquid outwards, and so it is discharged through pipes leading from the casing.

Chain.—The various types of chains will be found under the headings of "Block," "Silent," and "Roller Chains." It is enough here if we compare the different types. The block chain, is now comparatively old-fashioned and gone out of use for motor work, having been superseded by the roller chain, which is considerably more efficient. The roller chain, however, stretches and then makes a crackling noise, caused by the fact that, owing to the general stretch, the rollers encounter the teeth of the chain wheel too much on the top and consequently finally spring down into their place with a jump instead of quietly rolling over them. To obviate this, the inverted tooth type of chain has been introduced, for this type is practically independent of alterations of the pitch, within reason.

Chain Adjuster.—A device by which the centres of the chain driving and driven wheels may be altered relatively to each other to allow for the stretch of the chain.

Chain Pitch.—The pitch of a chain is the distance from the centre of one link to the centre of the next, and the pitch chain wheel is the distance from a point on one tooth to the corresponding point on its neighbour.

Chain Sprocket.—The toothed wheel by which the power and motion of the engine is transmitted to the chain.

Chain Transmission.—Used to be very largely employed in car design, but the introduction of the live axle has largely put it out of court, except for heavy utility vehicles, and even here it is losing ground. The most usual form of chain transmission was by side-chains. In this arrangement the engine, through the usual gear-box economy, drove a cross counter shaft fitted with balance or differential gear, so that each end of the counter shaft could move independently of the other. Each end was fitted with chain sprockets, and from these the power was separately conveyed to chain-wheels on each of the back road wheels of the car. Sometimes chain transmission is employed with a live axle, the driven chain wheel being secured to the casing or spider of the balance gear. In certain cars, too, it is adopted to transmit the power from the engine to the gear box while in the latest type of omnibus each separate speed in the gear box is driven by a very short inverted tooth type of chain. Chains of the inverted tooth type are also coming into growing use for the driving of engine camshafts and magnetos.

Chain Wheel.—A toothed wheel that is driven by a chain. These chain wheels are generally secured to the road wheels.

Change Speed Gear.—See **Gear Box**.

Change Speed Lever.—The lever by which the change from one gear to another is operated. This is usually placed at the side of the car close to the brake hand lever, but on certain cars it is placed on the steering column beneath the steering wheel.

Channel Iron or Steel is so called when rolled to a sort of trough section. The various parts of the ordinary pressed steel frames on cars are of this section.

Charge.—The supply of air and fuel for the cylinders of an engine. To charge accumulators with electricity they should be charged at a ten-hour rate, suitable resistance being interposed in the circuit, if necessary, to give this rate of charging.

Chassis.—There is no absolutely hard and fast definition of Chassis. Some makers seem to think a chassis includes the wings or mudguards and foot-

boards; others take a less liberal view; but for general purposes it may be defined as the complete mechanical department of a car as distinct from the body.

Check Valve.—A valve which will only allow of flow in one direction—A non-return valve.

Choke.—Where the petrol issues from the carburettor let it is desirable to bring the air for the charge into contact with it, and therefore the passage by which the air passes is generally contracted at about this point, which is accordingly called the choke.

Chrome Steel and Chrome Nickel Steel are materials which have come to be a good deal used for car construction, in such details as the gears, crank shafts, etc., as both these materials are exceedingly strong and tough, and do not suffer from fatigue, or what is popularly described as "crystallisation of the metal," in the same way as steel or iron.

Circular Pitch.—The distance from the centre of one tooth to the centre of the next in gear or chain wheels.

Circulation.—Complete and uninterrupted flow in a circuit. The word is generally applied either to the flow of the cooling water from the cylinders or to the flow of lubricating oil—more generally the former.

Clearance.—When there is room for one moving part of mechanism to move past another, or past a structural part of the mechanism, there is said to be clearance between the two parts is known as clearance.

Clinometer.—An instrument for measuring the steepness of a gradient or hill.

Clip.—A spring fastening used in rubber pipe connections, especially for those on the water circulating system.

Clutch.—A device by which the power of the engine may be transmitted at will to the gear box and car wheels. If we except one or two unusual types, such as magnetic clutches, the clutch invariably depends on friction. One part of the clutch is secured to the engine shaft and rotates with it, the other part (which is free when the clutch is out of action) being capable of being slid longitudinally along its shaft into such hard and close contact with it that the two parts grip together, so to speak. There are conical, plate and expanding types of clutches, for which see under these headings.

Clutch Stop.—When a clutch is taken out for change of gear, it often happens that the clutch shaft and with it the primary shaft of the gear box is revolving too rapidly, owing to the momentum already imparted to it by the engine; accordingly, a clutch stop is often fitted to cope with this difficulty. It is in fact a small brake which, when the clutch is pulled far out of engagement, reduces its rotation speed and that of the clutch shaft to one more suitable for gear changing.

Coach Work.—See **Body**.

Cook.—Another word for tap.

Coli.—A coil is a transformer for increasing the voltage of current, or rather for inducing higher voltage. This increase of voltage depends on the windings of the coil and is proportionate to the number of the windings of the secondary coil relatively to those of the primary. If a current of 4 volts on the primary circuit is passed through a coil in which there are one thousand turns or windings of the secondary coil to every one of the primary, a current will be induced on the secondary circuit equal to 4,000 volts, and so on. The word "coil" is also used in connection with springs such as are used for valves (ordinary helical springs) while tubes are sometimes made up in coils for radiators, burners, or boilers.

Collar.—A projecting ridge, either formed solid on a shaft or by a ring on the shaft. It may really be described as the reverse of a groove in a shaft.

Combustible Mixture.—When inflammable fuel and air are mixed in correct proportions they will burn, and will burn so rapidly that their burning constitutes an explosion—which is after all only extremely rapid combustion. For practical purposes the best mixture with petrol is 1 volume of petrol to 12 of air.

Combustion.—In an ordinary steam engine combustion means the burning of the fuel in the fire box. In internal combustion engines it refers to the explosion of the fuel in the cylinder.

Combustion Chamber.—The space in the cylin-

der above the piston in which the explosion takes place.

Commutator.—Reference to "Alternating Current" will show that the natural tendency for a dynamo is to give an alternating current, with impulses first in one direction and then in the other. To obtain a continuous current, every other impulse should be reversed, and to this end a commutator is fitted. The word has got somewhat misused, and is often applied to the contact maker and breaker for the ignition.

Compensating Mechanism.—It is desirable that the braking force of the wheels on each side of a car be equal, and to ensure this the braking power is frequently transmitted through compensating mechanism. This is usually effected through a compensating lever, which is similar in principle to the beam of a balance. The pull of the driver's brake lever is transmitted to a point at the middle of the compensating beam, which may lie transversely across the car, and from each end connection is made to the brakes on one of the wheels. Sometimes a mechanism similar to that of a balance gear (see under this heading) is employed for the same result.

Components.—The larger parts, such as axles, springs, etc., that go to the making up of a car.

Compound Engine.—A compound engine is fitted with two sizes of cylinder. There is the high pressure cylinder of comparatively small size, and the low pressure cylinder of about double that capacity. Its principle is this:—after the steam has done its work in the high pressure cylinder, instead of exhausting into air as in the ordinary engine, it exhausts into the low pressure cylinder. As the steam (for at present the system is practically confined to steam) has to fill more space, it has a certain amount of freedom in exhausting into the larger cylinder, where it works at a very much lower pressure; but as it works on a much larger area of piston, the power results in each cylinder being roughly speaking, much about the same. It must not be thought that the steam is used twice over. That is a misleading way of putting it. The compound engine only enables the steam to be worked more expansively than would be possible in a non-compound engine.

Compression.—When the mixture of fuel vapour and air, which by its explosion drives the engine, is at the moment of explosion compressed, it results in an explosion of considerably more force. Consequently, in ordinary practice it is customary to compress the charge before firing it. Though a lot of the engine energy is wasted by thus compressing the charge, the gain of extra power from a compressed charge explosion exceeds the work lost in compression.

Condenser.—In a steam engine a condenser is a device whereby the exhaust steam, instead of being allowed to pass out into the atmosphere and be wasted, is cooled and transformed back again into water which can again be used in the boiler. A condenser, therefore, enables a car to travel much further distances without the necessity for stopping to take in fresh water supplies. The condensing action may be obtained either by air-cooling as with a radiator, or by exhausting the steam on surfaces cooled by water. In the latter case the water supply carried by the car can be used and thus a condenser may, to a limited extent, also be made to heat the feed water, and thus economise heat. In electrical ignition we also find condensers. Here a condenser is the equivalent of an air vessel on a water pump. It gives a stronger spark at the plug, and prevents sparking at the contact maker points.

Conduction.—When one particle of a substance has more heat than its neighbour, the heat tends to equalise matters and to flow from the one to the other, and even when two bodies of different temperatures are placed in contact the same thing happens. This process goes on from particle to particle until the whole substance is at a uniform temperature. Conduction is in fact the transferring by contact of heat, due to difference of temperature.

Compound Wound.—When the windings of the magnets on a dynamo are formed by both series and shunt circuits, the machine is said to be compound wound. See **Series Wound** and **Shunt Wound**.

Cone Clutch.—In this type of clutch—the most

common—a large diameter circular cone, usually leather covered, is made to slide axially at will into engagement with a hollowed out conical cavity in the fly wheel, the friction being obtained between the sloping walls of the cavity and those of the cone. The angle of these surfaces should be at about 12° or 13° with the axis of the engine shaft.

Conical Valve.—Valves of the poppet or mushroom type (the latter name best describes them) are generally chamfered or bevelled off all round their lower circumference where they fit on their seatings, the seating being chamfered at a corresponding angle. The seating thus tends to centre the valve dead true on to it. An angle of about 45° is the most suitable for the bevel or chamfer in such cases.

Connecting Rod.—The connecting rod is that part of an engine which transforms the reciprocating, or up and down movement, of the piston into the circular motion of the crank shaft. The end which is secured to the piston and moves up and down with it, is free to swing, and thus enables the other end to follow the circular path of the crank pin, which is provided with bearings, enabling the rod to grip the crank pin loosely enough for the crank pin to turn in the bearings, and tightly enough to prevent any shake or "knock." Owing to balancing requirements the weight of the connecting rod should be kept as low as possible consistent with strength, and that is why connecting rods are usually made of hollow tubular form or of H section.

Contact Blade.—The spring blade of the contact maker.

Contact Maker.—Contact makers are of two sorts, the "make and break" and the "wipe." In the former a rapidly revolving cam on the half-time shaft, acting on a plate spring, moves the latter against a contact screw, so that the circuit is quickly made. The projection or depression in the cam rapidly passing on, then leaves the spring free to jump away quickly and break contact. This rapid make and break is essential to get a good spark. The plate is shod with steel where it bears on the cam, and fitted with a little piece of platinum where it makes contact. In the wipe contact a steel-shod spring wiper bears on a circular contact maker. This is of insulating material except at one point, where a metal plate, connected metallically to the frame, is let in. When the shaft on which the contact maker, in revolving, brings the wiper into contact with this place, the circuit is joined up, but it is necessary to break it to get a good spark at the plug, and therefore the coil in wipe systems is fitted with a trembler, for which see under this heading. On a magneto a contact maker is also fitted.

Contact Platinum or Point.—The platinum point on contact screws, or the platinum on the blade. These should be kept clean and free from pitting to ensure their making good contact.

Continuous Current.—An electrical current is continuous when it flows entirely in one direction—the reverse of an alternating current—and when taken from a dynamo the continuity is assured by means of the commutator.

Control.—Broadly applied to all the means of regulating the car when in action, but to some extent it is narrowed down to apply merely to the levers by which such regulation is carried out, especially those that regulate the engine.

Convection.—When fluid is heated locally, the part heated has a tendency to rise above the rest, this tendency being in general proportionate to the heat applied. This can be seen by boiling fluid in a test-tube, when that at the bottom, which is most strongly heated, rises rapidly to the top. This is known as "convection." When the fluid rises, its place is filled by cooler fluid, and this state of affairs, constantly going on, results in currents being set up which are known as "convection currents." The principle of the convection current is being largely used for circulating the water that cools the engine cylinders, the details of which will be found explained under the heading of "Cooling System."

Cooling System.—The heat generated in the cylinders of an explosion engine is such that, unless it

were counteracted it would burn all the oil, and result in the piston sticking tight in the cylinder. Means are taken to reduce this heat either by cooling the cylinders with a rush of air, or by surrounding the cylinder barrels with water that, as fast as it becomes heated, is taken away to be cooled and replaced by already cooled water. Water cooling may be carried out either by forcing the water through the cylinder jackets with a pump, or by using the natural circulation that the convection currents set up. This last is called the thermosiphon system.

Copper.—A metal that chemically is an element and known by the symbol Cu. In motor work it is usually used in sheet or tubes. Copper is also very useful in plating, for to get the best effect, silver and nickel should be deposited on a film of copper, with which the object to be plated is first covered.

Cotter.—Usually applied to a tapered pin, either flattened or round in section, chiefly used for fixing collars, levers, etc., to shafts.

Counterbore.—When a hole is driven for the accommodation of a rivet or bolt, and it is undesirable that the head of the rivet or bolt should project above the surface, the hole is counterbored; that is to say, at the end of the hole a cavity is made to accommodate the head of the rivet or bolt.

Coupe.—An entirely enclosed type of body. The term is often applied to two-wheeled enclosed bodies, either of the cabriolet or limousine type.

Couple.—When two forces act around a point the one on one side acting in one direction, the other on the other side of the point acting in the other, the two, if acting in connection together, or acting on the same body, would tend to twist that body around the point. This is called a couple, an excellent illustration of which is afforded by the action of a driver at his steering wheel: when he turns his wheel, on one side of the centre the one hand pulls in one direction, on the other side of the centre he pushes in the opposite direction with the other hand, the whole turning the wheel round.

Coupling.—See Joint.

Crank.—If a shaft, intended to rotate, is bent in such a way that the bend affords an arm which acts as a lever for turning the shaft round, it constitutes a crank. The bend may be at the end of the shaft or in the middle—it is still a crank. A good example of the principle of a crank at the end of a shaft is found in the starting handle, but in engine shafts, as they usually have to be supported on both sides of the bend, the shaft is formed with a bend or "throw" in it so that the length of shaft on one side of the throw is in alignment with that on the other. Also, as the connecting rods have to work at right angles to the shaft these throws must be formed with a bearing along their middle part that is parallel to the shafts. The throw of the crank, that is to say, the total diameter of the circle traversed by the crank bend in a single revolution of the shaft, equals the stroke of the cylinder, a factor upon which the power of the engine largely depends. A crank shaft should be of tough steel, and requires to be most carefully made to obtain good results. In motor-cycle engines where only a single throw is required the crank is formed of two flywheels joined by a crank pin, and with concentric steel journals that correspond to the shaft journals.

Crank Bearing.—The main bearings of a crank shaft sometimes placed intermediately between the crank throws and at each end. On many engines a bearing is only placed between each pair of crank throws, and some crank shafts of four-cylinder engines only have bearings at the ends, although this involves a very massive crank shaft.

Crank Case or Chamber.—The enclosing part or the casing in which the crank shaft revolves.

Crank Cheek, or Crank Web.—The side of the crank throw between the crank shaft and the crank pin.

Crank Effort.—See Torque.

Crank Handle.—A term sometimes applied to the starting handle, but equally applicable to any handle on the crank system.

Crank Pin.—The journal that rotates in the big end bearings of the connecting rod, and is usually placed between the crank cheeks.

Crosshead.—In double acting steam engines, in

which a piston rod carried through a gland in the front cylinder cover has to be used, a special forward connection is fitted to enable the connecting rod and piston to be suitably connected together. Also, the crosshead not only serves as a connecting link between the piston rod and connecting rod, but also offers convenient surfaces for applying to the guide rails which ensure perfectly straight motion for the piston rod.

Cross Member.—A term usually applied to the tubes or lengths of pressed steel lying across the frame.

Crown Wheel.—The large bevel wheel secured to the differential casing of a counter shaft, or back axle, which is driven by a bevel pinion from the propeller shaft.

Crucible Steel.—Another name for tool steel, which is made of blister steel melted in a crucible.

Curve.—See Diagram.

Cushioning.—In a steam engine, with a piston moving backwards and forwards rapidly, it is desirable at high speeds to admit steam for, say, the outward stroke, before the piston has quite finished its inward stroke, and this has an effect on the rapidly reversing piston, described as "cushioning."

Cut Off.—In the cylinder of a steam engine the steam is not usually supplied from the boiler during the whole of the stroke, for it is found much more economical (considering the amount of power obtained for the amount of steam used) to cut off the supply when the piston has traversed only a part of the stroke ranging anywhere from 15 per cent to 75 per cent. of the total stroke. (See *Expansive Working*.)

Cut-Out.—In car electric lighting systems the dynamo, if driven at a suitable speed, can charge the accumulators, but when the car, and consequently the dynamo, runs very slowly, the latter does not generate enough electricity to charge the accumulators. If nothing were to prevent it, the current would then flow out from the accumulators to the dynamo instead of the other way, with damage to the dynamo windings. To prevent this a device known as a "cut-out" is employed, automatically to disconnect the dynamo and accumulators as soon as the speed of the former falls below a certain point.

Cycle of Operations.—In internal combustion engines at present either of two principles is adopted. These are known as the four-cycle and the two-cycle. In the cylinder of a four-cycle explosion takes place only every fourth stroke, or every two revolutions. In a two-stroke engine an explosion is given every two strokes, in other words, in every revolution. (See *Four Cycle Engine* and *Two Cycle Engine*.)

Cylinder.—The tubular shaped part of the engine in which the piston is driven up and down.

Cylinder Capacity. is the amount of volume of gas that a cylinder can hold. It is made up of the cubic capacity of the combustion chamber together with the volume swept by the piston in its stroke.

Damping.—Damping is the process of deadening the shock of sudden movement. Dampers are often used on the springs of cars to check their rebound.

Dashboard.—The board or panel in front of the driver. It is a term borrowed from the horse vehicle, but on the motor car affords accommodation for the various gauges and many of the fittings such as lubricators, etc.

Dashpot.—A dashpot is a means of damping sudden motion, the usual form consisting of a piston, moving in a cylinder and checked in that movement owing to the fact that fluid, allowed into the cylinder, can only escape at a certain rate. The presence of the fluid acts as a brake on sudden piston movement.

Dead Centre.—When the crank pin is at a point nearest to or furthest from the cylinder, and the centre line of the crank web is in line with the centre line of the connecting rod, any thrust transmitted through the latter from the piston exercises no useful turning effect, since the thrust is purely radial without any tangential tendency. When at either of these points the crank is said to be on one of its dead centres.

Declutch.—To take the clutch out of engagement.

Deflection.—The deformation due to bending stress.

Deflector.—Another name for a baffle plate.

Delivery Valve.—A valve which allows fluid to pass the supply opening from a pump.

Demagnetise.—In the process of time and use the magnetism of a dynamo or magneto magnet becomes weaker and weaker, and this process is known as demagnetisation. When they become too weak they have to be re-magnetised by passing an electric current around them.

Denaturise.—To render undrinkable. The word is used particularly in connection with the manufacture of alcohol for industrial purposes.

Densimeter.—Sometimes known as hydrometer, is an instrument for measuring the density of liquids, and used to be much employed by motorists for testing the density of their petrol.

Detachable Rim.—An ordinary artillery wheel is made up of the hub, spokes, felloe, and rim, which latter holds the tyre. To facilitate tyre repairs, the rim is sometimes made quickly and easily detachable from the rest of the wheel, if the whole wheel is not made detachable.

Detachable Wheel.—A wheel specially designed and made to be quickly and easily detachable. The possibility of tyre troubles are chiefly responsible for the advent of the detachable wheel which is now largely used.

Diagonal.—Some frames besides being provided with the ordinary longitudinal and transverse members are also made with diagonal braces or struts joining the end transverse members with the longitudinals. This is to guard against the frame being pulled out of square.

Diagram.—The curves on a diagram often afford a very useful means of showing a mechanical action graphically. These curves are quite simple to read. The actions they represent are usually made up of two main factors. We will take, for example, the action of gases in the cylinder. From moment to moment their pressure varies as from moment to moment they move the piston and so alter their volume in the cylinder. In other words we want to show the continuous change going on between pressure and volume. In a curve for this purpose, therefore, the horizontal distance usually represents the length of stroke, in other words, the volume that the gases have to fill—while the vertical height represents the pressure. If one wants to find the pressure at any point during the stroke one has only to take the vertical height of the curve at that point on the stroke as represented in the diagram.

Diametral Pitch is the unit form of measurement used for spur wheels and their teeth. The diametral pitch is the number of teeth to every inch of the diameter of the spur wheel.

Diaphragm.—A thin plate of flexible metal sometimes employed for regulating the flow of additional air to the engine. In such a case it is placed so that when the suction of the engine acts on it it bends, and this movement of the diaphragm is generally transmitted to a lever designed greatly to magnify the action, which when magnified is used for opening the additional air valve.

Differential.—See **Balance Gear**.

Direct Drive.—When the engine power is being transmitted direct to the gearing by which the back axle is directly driven, without the intervention of any other gear wheel, the drive is said to be direct. The term is not, strictly speaking, accurate, since the gearing of the live axle is interposed between the engine and the back wheels.

Dirigibility.—The capacity to be steered.

Discharge is the flow of electric current from accumulators, which has the effect of lowering the voltage. Great care should be taken that accumulators are not discharged too rapidly, for too rapid discharge tends to buckle the lead plates.

Disengage.—Usually applied to the clutch, when it means to take out of engagement. It is sometimes also applied to gear wheels when it means to take one gear wheel out of mesh with another.

Distributor.—A device arranged to enable a single-cylinder coil to be used on multi-cylinder engines. As the contact maker acts for each separate cylinder the current ordinarily has to be transmitted to each separate coil, whence it is carried to each separate plug. With a distributor high tension current is supplied from a single coil straight to the distributor, which, with its revolving part then makes contact so as to pass the current first to one sparking plug then to another, and so on in due rotation.

Distribution Gear.—Comprises the shafts that operate the valves and ignition of an engine, together with the gear wheels through which they are driven.

Dog Clutch.—With a dog clutch the one member is put into engagement with the other by sliding it up against the other so that jaws or arms (projecting longitudinally along the axis from the end faces of both members) engage with each other.

Double Acting.—A double acting engine is an engine in which the power is applied first to one side, and then to the other of the piston. At present the internal combustion engine has not reached the stage of being double acting for road transport, but the principle is commonly applied to steam engines.

Drain Cock.—A tap usually at the bottom of the crank case to draw off superfluous oil as required, but the word is also applied to cocks leading from the bottom of steam cylinders and steam valves to enable water to be drained from these parts.

Drive.—Signifying transmission or power.

Dual Ignition gives the use of two forms of ignition. It is usually used to facilitate starting, in which case the ordinary accumulator ignition is employed in conjunction with magneto; the former enabling an engine to be started better than on the magneto. Sometimes, however, where exceedingly great reliability is required, dual magneto ignition is adopted.

Drum.—The rotating part of a brake, against which the shoes are pressed to retard the car.

Dry Cells are used in primary batteries to supply electricity, in cases when it is desirable that the batteries should be made up of components that do not spill.

Duct.—Another word for a passage for petrol, etc.

Ductility is the capacity of a metal to be drawn out under a hammer, or in the rolling mills.

Dumb Iron.—The pieces of metal, usually forgings, that form an extension of the frame longitudinally and at the same time act as a bracket to carry the front ends of the springs at the back or front.

Dynamo.—A machine for producing electricity, which it does by means of an armature driven round between the poles of a magnet or magnets. Each time each coil in the armature cuts across the magnetic lines of force between the poles of each magnet electrical current is set up. Broadly speaking, dynamos are of two sorts—alternating and continuous current—for which see under these headings.

Dynamometer.—An instrument for measuring power. The dynamometer as we know it to-day is usually employed for measuring the brake horse-power of engines, and is virtually a brake for absorbing by friction, and measuring the power given by the engine.

Dynamos.—An electric motor is merely a dynamo reversed. As the former, it can produce by the rotation of its armature a flow of current along a circuit, but if the process be reversed, and current be passed along the circuit, it can rotate the armature and thus convert the dynamo into an electric motor. Each type of machine is generally specially designed for its own purpose, but in a "dynamotor" we find the two functions combined, usually as a dynamo for lighting and a motor for engine starting.

Earth.—In certain ignition systems the current is, at one point on its journey, taken through the frame of the vehicle, and as far as motorists are concerned, that part of the circuit represented by the frame of the machine is the earth, for it is supposed to pass through the earth on its return. The phrase is somewhat of a misnomer.

Ebonite is a non-conducting substance used in electrical work for insulating purposes. It is black and capable of taking a high polish, but, though tough up to a point, will not bear any great heat.

Eccentric.—An eccentric is a device for converting the rotary motion of a shaft into the reciprocating motion of such things as pump pistons, etc. It is in reality a crank with the crank pin diameter so enlarged as to surround even the shaft the centre of which, of course, does not coincide with that of the exaggerated crank pin or eccentric; hence the name. An eccentric is composed of two essential parts; the sheath and strap—the sheath being the equivalent of the exaggerated crank

pin, and the strap corresponding to the bearing of the big end of the connecting rod, for the eccentric rod is rigidly connected to the strap. The shaft rotates in the strap, and in so doing imparts a reciprocating movement to the eccentric rod. The strap is usually formed with lips on each side fitting into corresponding grooves on the shaft, to obviate sideways motion.

Efficiency is the ratio between the ideal and the actual in certain qualifications, such as the capacity for converting heat into work, speed into power, and so on. Among the usual efficiencies, to be dealt with in motor work, is thermo-dynamic efficiency, which means the ratio of heat as represented by work, given out by the engine compared with the heat primarily supplied to it. Mechanical efficiency is another typical case. This, of course, applies to the mechanism of the engine and represents the amount of power actually given off usefully by the engine at the crank shaft, as compared with the actual power indicated in the cylinders; in other words, it gives an indication of the loss caused by the mechanism intervening between the crank shaft and the cylinder. Transmission efficiency is another frequent example. More power has to be put in at the driven end of a transmission system than comes out at the driving end, a certain amount always being wasted in friction, etc., and efficiency then becomes a measure of the power lost. Efficiency is usually stated by giving the percentage of the real in terms of the theoretic maximum.

Electric Car.—A road car driven exclusively by electricity. This always means a car driven by electric motors supplied with electricity from batteries carried on the car, and changed every 40 miles or so as a rule, although vehicles have been known to run more than 200 miles on a single charge. For heavy work such as motor omnibuses, however, electric vehicles are occasionally used in which the current for the dynamo is supplied from a central station through an overhead wire and swivelling trolley pole, as in tram-car practice.

Electric Ignition.—See **Ignition**.
Electric Lighting System.—Usually in the main made up of a dynamo and accumulators, with an automatic cut-out (see **Cut-out**) to disconnect dynamo as soon as its speed falls below a certain point. The electric light system also includes a means of checking the dynamo output above certain speeds, so as to maintain a constant output in spite of varying car speeds. This regulation of mechanism output is usually effected by the arrangement of the windings of the dynamo.

Electrolyte.—The acid contained within the cell of an electric battery.

Electro-Magnet is a magnet in which the magnetising force is generated or greatly intensified by an electric current passing around the magnet.

Elliptical Springs.—See **Springs**.

E.M.F.—The same as voltage or difference of potential.

Engine.—For motor work two media are used for driving purposes, steam and explosive pressure of gases, the latter being primarily obtained within the cylinders of the engine, which are therefore called internal combustion engines. Steam engines may be double or single acting, that is, the steam may act on one side of the piston or alternately on both sides, each double acting cylinder having twice the frequency of impulse of a single acting. Also steam engines may be non-compound or compound (see latter heading). Internal combustion engines for car work usually obtain their power by the explosion of petrol with air, but some use paraffin, and a few run on alcohol or benzine. At present they may be either of the two or four cycle type (see these headings).

Engine Brake.—A device by which the compressive power of the engine cylinders can be used for retarding the progress of the vehicle.

Engine Starter.—See **Self-Starter**.

Epicyclo Gear.—A form of transmission in which speed variation is obtained through driven gears arranged to rotate or travel around the driving gear, whence the revolutions of the gear are again transmitted to a shaft in alignment with the driving shaft. On its high speed the gear is usually arranged so that the driving effort is balanced in two opposite directions and thus the gear locks itself and revolves as a solid mass giving direct gear. The changes are usually

effected by bringing into action brakes or clutches affecting the different gear variations.

Evaporate.—To convert a liquid from its liquid form into vapour or gas.

Exhaust.—The waste gases from an engine.

Exhaust Pipe.—The pipe by which the exhaust gases flow from the cylinder.

Exhaust Port.—The passage by which the gases flow from the cylinder to the exhaust valve chamber.

Exhaust Stroke.—The half-revolution in an engine during which the exhaust valve is held open and the piston on its stroke is sweeping out the products of combustion past the exhaust valve.

Exhaust Valve.—The valve to regulate the flow of exhaust gases from the cylinder.

Exhaust Valve Lifter.—A device, generally employed on motor cycles, for holding the exhaust valve more or less open, and so relieving the compression in the cylinder. It can be used to overcome the compression and facilitate starting, or to regulate the speed of the engine by weakening the explosion effect, although for this latter purpose the throttle and spark variation lever are preferable.

Expanding Clutch.—A friction clutch in which shoes, by means of toggle joints or other mechanism, are made to press tightly against the inner circumference of a drum, whence the movement is transmitted to the shaft to which the shoes are secured.

Expansion.—The tendency to increase in volume.

Expansive Working.—When a certain volume of gas is in a cylinder fitted with a piston, it tends to push the piston outwards, which in turn leaves a larger space for the gases to fill. If no more gases are allowed to enter, those already in the cylinder, having to fill a larger space, will fall in pressure as they continue to push the piston out. The principle is most evident in steam working. Suppose steam from the boiler is admitted into the cylinder freely until the piston has completed a quarter of its stroke, and steam supply is then cut off. By the time the half stroke is reached the steam will have to fill twice the space, and therefore, roughly speaking, will be at half the pressure; by the time the full stroke is reached, the steam will be at about a quarter of its original pressure. Although a cylinder working like this does not give off as much power as one in which full boiler pressure is supplied throughout the stroke, it can be shown that by this expansive working very much more power can be obtained for the amount of steam employed. In fact without the possibility of expansive working the steam engine would not be a commercial proposition.

Explosion.—Explosion is really only burning in a very sudden form, and consequent sudden expansion of gases. In motoring, the word is invariably applied to the combustion taking place in the engine cylinders, although if the inlet valve does not shut quickly enough, these explosions may spread to the carburettor on the one hand, while if the engine is missing fire and so sending unburnt charges into the silencer, an explosion from the engine, flashing into the silencer, may ignite the hitherto unburnt charges in the silencer and cause an explosion therein.

Fan.—A device similar to the ventilating fans (with which all are familiar) is often placed behind the radiators to encourage the flow of cooling air by rotating at high speed. These fans are usually driven by belt from the engine, but in some cases the fly wheels of the engine are formed with spokes shaped so as to take the place of the vanes of the fan.

Faucet, the same as **Spigot**, which see.

Feather.—A key, usually a long one, but so arranged as to permit the wheel or other fitting that it secures to the shaft being slid along, at the same time compelling it to rotate with the shaft. Sometimes the feather is secured to the sliding fitting and slides in a long groove cut in the shaft.

Feed.—The supply of oil, fuel, or water. It may be fed from the tank to the carburettor by gravity or by pressure obtained from an engine driven pump, or from the exhaust to the engine. The same applies also to the oil. The term water-feed is used in connection with steam engines in which the water is supplied to the boiler by a pump or by an injector.

Felloe.—The wooden rim of a wheel into which the

outer ends of the spokes butt, which in turn is surrounded by the steel rim, which constitutes the tyre in the case of hard tyre vehicles and which accommodates the tyre in the case of indiarubber shod vehicles.

Fibre.—A hard material produced by secret manufacture from vegetable fibre, and used chiefly for insulating purposes, although it has been used for clutch surfaces and brake shoes. Fibre can be cut by tools suitable either for wood or iron. It is usually of a reddish colour, although black and even grey fibre can be obtained.

Filter.—An arrangement for arresting the passage of foreign matter that may be in the oil or petrol. Filters are usually placed in the inflow of a tank and are composed of fine wire gauze. In many systems of lubrication, however, the filter is located at the bottom of the engine crank case. In such instances the filter should be withdrawable without letting any of the oil out of the crank case. In the writer's opinion the single filter usually used is not sufficient, and two or three might with advantage be introduced in the circuit followed by the oil or petrol.

Fire Box is that part of a boiler in which is the fire that raises the steam.

First Speed.—The lowest forward gear on a car.

Flanged Joint.—When the ends of pipes or other similar parts are provided with annular discs, the bases of which, butting up against each other, are clamped together by screws (thus securing the pipes together), the joint is described as a flanged joint. The flange may also be used to secure the pipe to any flat surface. Note, for instance, the way in which exhaust or inlet pipes are held to the cylinders of many engines.

Flexible Shaft.—For very light work, as for example the driving of a speedometer, a flexible shaft is used. It is often joined on the same system as that used by dentists for their drills, and is more or less an encased coil of wire or strip metal, which, while capable of bending, will transmit rotary movement.

Fifth Plate is a deep flat plate of metal bolted to the side of wooden frame members to strengthen them. The wooden frame and fifth plate is seldom, if ever, made now.

Floot Chamber.—See Carburettor.

Floot Spindle.—The spindle which is moved by the float when it rises, and which shuts off the petrol supply.

Flooding.—To ensure that the engine shall get a proper supply of fuel at starting, it is sometimes customary to hold the float spindle off its seating in order to fill the carburettor with fuel. Sometimes the spindle is "joggled" up and down; this is known as "tickling" the carburettor.

Flush Sided Body.—A body in which the sides are without any sudden projections or depressions.

Flux.—See Brazing and Welding.

Fly Wheel.—A heavy wheel or at any rate a wheel with a heavy rim—secured to the crank shaft of the engine. The weight of the wheel or its rim, once the engine is moving, tends to keep it moving, and thus by the momentum of its mass keeps the shaft rotating during the intervals between the impulses.

Fore-car.—The front two-wheeled attachment fitted to motor cycles for carrying passengers, etc.

Forced Circulation.—When lubrication & the cooling water is circulated by a pump or other means of pressure, the circulation is called forced.

Four Cycle Engine.—An explosive charge if compressed—although that compression, by the resistance it causes, takes up a certain amount of the engine's energy—yields more additional force in its explosion than is lost in the power necessary for compression. Consequently it is desirable to work the internal combustion engine with a compressed charge if possible. This discovery, which is ascribed by some to Beau de Rochas and by others to Otto, involves each cylinder having an explosion once in every two revolutions, or every four strokes; whence the name. On the outward stroke of the piston the explosive charge is sucked in, on the return stroke it is compressed, and when the piston is just at the top

of that stroke the charge is fired. The resulting explosion drives the piston outwards to the end of its stroke, and as these strokes of the piston are continually turning the crank round, and the crank is fitted with a flywheel, the momentum of this flywheel keeps the crank and pistons moving while the latter are doing their unprofitable strokes. Before the bottom of the explosion stroke the exhaust valve opens, and the burnt gas escapes, being completely swept out on the upward exhaust stroke. The cycle of operations is then repeated.

Forged Metal.—Metal that has been shaped by heating and then put under the hammer or hydraulic press.

Frame.—The structural part of the car which carries the mechanism and body. It is usually an arrangement of longitudinally and transversely arranged pressed steel members, but steel tubes are still used, though not so much as in the past. At one time wood, strengthened by steel ditch plates, was employed.

Friction Clutch.—See Clutch.

Friction Gear.—A form of change speed transmission depending on the friction between two wheels, instead of on the teeth of gear wheels; the idea underlying the use of friction gearing being to obtain an infinite variation of speed within certain limits. In the ordinary friction gear a flat cast iron disc of large diameter is driven by the engine, and bearing hard against its face is the rim of a leather-covered wheel, the friction between the cast iron and the leather circumference transmitting the power. Provision is made to alter the position of the leather-rimmed wheel to any point between the centre of the wheel (at the centre of the disc obviously no motion is transmitted) to the outer edge of the disc face, where the maximum speed is obtainable. From the shaft on which the leather-rimmed wheel is secured the power is transmitted for driving the car.

Front Brakes.—In order to obviate side slip there is still a tendency at present to brake the front wheels, but, as they have to be free to be swivelled for steering purposes, the problem is not an easy one. The difficulty is, however, overcome by passing the rod that operates the brake shoes through the centre of the steering pivot around which the entire wheel swivels.

Fuel Consumption.—Usually this is regarded as the number of miles that a car will travel for each gallon of fuel consumed, amounting in the case of a 15-gal car to about 20 miles a gallon on an average. The system of basing fuel consumption on car mileage is, however, not altogether scientific, a better method being to calculate the number of tons—miles, or tons moved over a given number of miles, by a gallon of fuel.

Fulcrum.—The point around which a lever or any part acted upon by a couple (see Couple) tends to turn. The same as a pivot.

Gallery Pipe.—In some forced lubrication systems the oil is led along a pipe in the crank case, having small holes in it just opposite the cams or big end bearings so that the oil is squirted from these holes on to the parts that require oil. Such a pipe is sometimes known as a gallery pipe.

Garage.—A French word meaning a dock, borrowed in this country to apply to a shed for housing motors, and frequently extended to embrace an establishment where motors are housed and repaired.

Gas.—A term sometimes applied to the explosive mixture for the engine.

Gate Change.—In the ordinary gear box mechanism, the various gear striking rods, operating the gears in the gear box by sliding them, lie horizontally and parallel with each other, and are formed with a cross groove near the end along which the selector can pass, if the selector has to reach another gear, or in which the selector can remain if that particular gear is to be used. The gear is then changed by a fore and aft movement of the lever and the striking rod. It is therefore clear that the change speed lever has to rock in a transverse direction to operate the selector, and then in a fore and aft direction to change the gear and thereby regulate the movements of this lever. A

specially shaped quadrant is fitted with slots into which the lever fits, and in which it is held for the respective changes of speed. Another gear fitted with this system of change speed mechanism are said to be fitted with a gate change.

Gauge.—An instrument for testing measurements: usually in motors gauges are for testing measurements of pressures such as air or steam boiler pressure. This type of gauge is usually provided with a calibrated dial on which the actual pressure at the moment is indicated by a deflecting needle. Another sort of gauge is used in workshop use for measurements of machine parts, as the diameter of wire, the thickness of sheet metal, etc. Some of these gauges for machining—known as "limit" gauges—afford a maximum and a minimum measurement beyond which the dimensions of the article to be machined must not pass in either direction.

Gauge Glass.—A glass tube fitted between brass mountings to enable it to be secured to the boiler of a steam vehicle in such a position as to show the level of the water in the boiler through the glass. The brass mountings are also provided with cocks by which the water and steam pressure can be shut off in case of the glass breaking, and to guard against this latter eventuality a guard of very thick glass or of wire woven glass is also sometimes provided.

Gear.—Strictly speaking the word is applied to mechanism for transmitting rotary motion from one to another shaft, and for converting speed into power more or less, or *vice versa*. Also sometimes used to indicate mechanism generally. (See **Gear Change**.)

Gear Box.—The casing in which the gear mechanism for converting the high rotation speed of the engine into lower speed and greater turning power for the propeller shaft is contained. It also holds lubricant for the gear wheels, which are almost invariably of the ordinary toothed type.

Gear Change.—Every wheel may be regarded as an endless lever usually working at a disadvantage, the leverage at which the power is applied being represented by the radius of the driving shaft while the leverage at which it is given out is represented by the radius of the wheel itself. Therefore, if the mean turning force of the driving shaft is, say, 5 lbs. acting at a radius of 1 inch, the power given off by a wheel of 5 inches radius, in mesh with the smaller wheel, is 1 lb. Obviously, therefore, a large diameter wheel on a driving shaft is at a disadvantage, while if driven it enables the power to be applied with a big leverage and therefore offers an advantage. In other words, if a large gear wheel drives a small one the driving force acting on the shaft of the small wheel is less than on the driving shaft of the large one, but the small one makes many more revolutions than the larger in proportion to its size. *Per contra*, if we have a small wheel of a diameter of 1 inch driving a larger wheel of 6 inch diameter, we obtain a very much slower speed from the driven shaft (the), but it is driven round with six times the power. Thus gear wheels can be used for converting speed into power or *vice versa*. Now the power of the car falls off disproportionately as the engine revolution speed drops. Consequently in going up hill, as the engine slows down, its power weakens. But this is just when the power is wanted; consequently a device for maintaining the engine speed on hills and under heavy work is desirable. The difficulty is got over by arranging gear wheels in the gear box, so that, on coming to a hill that slows the car down, gear wheels of suitable radius can be slid into engagement with each other. These gear wheels afford fewer revolutions of the propeller shaft relatively to the engine shaft than the higher gears used for driving on the level, thus enabling the engine's revolution-speed to be maintained with fewer revolutions of the road wheels, at the same time ensuring the road wheels being rotated with a power increased proportionately as the speed is decreased. This, roughly speaking, is the principle of gear change.

Gear Pump.—A gear pump is one in which the fluid to be pumped is forced through to the pump by the action of two rotary sets of vanes, which are practically nothing more or less than gear wheels, the

teeth of which, meshing with each other, act as the vanes of the pump, and force the oil through.

Gear Wheel.—A toothed wheel, whether of the parallel spur, the skew, the bevel, or worm variety.

Generator.—Another name applied to boilers, especially to those of the flash or semi-flash type. It is also applied to the vessel in which acetylene gas is generated from calcium carbide by the application of water to the latter.

Gilled Radiator.—A radiator made up of tubes which depend for their cooling upon a large number of very thin metal fins placed around the tubes in such a way as to conduct the heat rapidly away to the air from the tube and the hot water contained therein.

Gland.—A gland is, practically speaking, a little box formed around a rotating, or sliding rod, in such a way as to permit it to continue to rotate or slide, but at the same time to afford around the rod a perfectly gas, water, or oil tight joint, as the case may be. Glands are used around piston rods on the cylinders of steam engines to allow the piston rod to work in and out without any escape of steam. They are also used on the rotating shafts of water and oil circulating pumps to permit the shaft to rotate without the water escaping from the pump. They are usually formed with a circular cavity containing the fluid-tight packing. This can be forced as tightly as required against the rod all round by pressing it up (by screwing up the water end of the gland so that it is forced along the rod).

Governor.—A mechanical means of preventing the rotation speed of an engine from exceeding a certain set maximum. This is usually effected by weights, which are so arranged that, when rotated above a certain speed by the engine, they fly so far outward by centrifugal force as to slide a spring-controlled sleeve sufficiently far along the shaft to which they are secured, as to slow the engine by shutting or tending to shut the throttle.

Graphite is a form of carbon, a good deal used as a lubricant for surfaces exposed to great heat. Asbestos washers can also with advantage be painted over with graphite to prevent them sticking to their joints.

Gravity Feed.—When the supply of petrol, or oil, depends on the weight of these fluids flowing from a tank placed at a higher level than the point at which it has to be fed, the liquid is said to be "gravity fed."

Grease Cup.—A more or less cup-shaped lubricator to hold and supply grease to parts of the mechanism. Grease cups are provided with covers which screw down and so force the grease through the opening at the bottom of the cup to that part of the mechanism requiring it.

Grinding in Valves.—When an engine has been running a long time the seatings of the valves tend to become worn and pitted, and it is then necessary to "grind the valves in" on their seatings. This is done by putting a mixture of the finest emery or crocus powder, with a little oil, on the seating of the valve, and then turning the valve round and round so that the emery grinds out all imperfections on the valve and seating surfaces. If the valve only rotated on its seating, the particles of emery would cover it over, or less to take the same circular path on each turn of the valve, and the grinding would, through a microscope, resemble a series of concentric grooves on the valve and its seating. To avoid this the valve should be lifted off its seating at every few turns to obtain a different disposition of the emery particles.

Grub Screw.—A small screw without any head but merely with a slot for a screwdriver cut at its end. Grub screws are used where it is necessary to have the screw flush with the surface without countersinking for a screw head.

Gudgeon or Gudgeon Pin.—The pin in the piston, on which the connecting rod at its small end is free to swing. It is generally secured immovably in the piston by taper locking bolts, or by having the gudgeon pin ends and the piston grooved to accommodate a locking ring, which passes around the piston and by its fit in the groove and the gudgeon pin ends prevents the latter from rotating. Sometimes the gudgeon swings with the connecting rod, and rotates in bearing surfaces in the walls of the piston.

Guide.—In a steam engine guides are usually bars of

steel to which the crosshead is secured as a sliding fit, and along which it slides. In internal combustion engines the guides are usually practically tubes in which the valve spindles and tappet rods slide.

Gun-Metal or Bronze.—An alloy used especially for bearings of shafts or bearing surfaces, such as guides, etc. It is composed essentially of copper and tin, sometimes with a little zinc, a typical mixture being 90 per cent. copper, 9 per cent. tin, and 1 per cent. zinc.

Gusset Plate.—A flat plate, usually triangular, riveted at the corners of motor frames to strengthen them and to guard the right-angled corners of the frame from distortion.

Hackney Carriage.—A Hackney Carriage, under British law, is a vehicle employed solely for the transport of passengers for its owner's business and profit, provided that the vehicle is not let for a term exceeding three months. There may be said to be two varieties of Hackney motor vehicle, the one a cab the other corresponding to the old horse-drawn fly. A cab is a Hackney carriage but a Hackney carriage is not necessarily a cab.

Half Time Shaft.—Usually the camshaft or distribution shaft. A shaft rotating once to every two revolutions of the crankshaft.

Half Speed Shaft.—A shaft geared to rotate at half the number of revolutions of the crankshaft. A term usually applied to the camshaft.

Hand Brake.—A brake worked by a hand lever, which usually operates on drums on the back wheels.

Head Lamp.—See **Lamps.**

Helical Gearing.—See **Skew Gear.**

Hemispherical Bearings.—To allow for the unavoidable "whip" in the frame of a car, some bearings, as, for example, those of the countershaft, are sometimes shaped outwardly to the curve of a circle, their housing being correspondingly shaped to accommodate them, so that the bearings may be allowed a certain amount of rocking motion, or "play," when the frame deflects.

High Pressure Cylinder.—See **Compound Engine.**

High-Pressure Engine.—A term sometimes applied to the ordinary non-compound steam engine.

High Tension Circuit.—When a circuit of low voltage on the primary circuit has been transformed through a coil or transformer into a high voltage current on the secondary circuit, it is called a high tension current, and the circuit along which it passes is called the "high tension circuit."

Hit-and-Miss System.—In some old cars the governor, instead of regulating the throttle, acts on a wedge-shaped sort of knife blade, which, at the critical speed, was forced forward by the governor to move the tappet rod of the inlet valve so that it did not come into contact with the valve spindle, and consequently the valve was not opened. This, of course, resulted in a fall in the speed.

Honeycomb Radiator.—Strictly speaking, the honeycomb radiator is made up of hexagonal tubes placed so closely together as only to leave room for very thin films of water flowing between their outer walls, while the air rushes through the tubes, cooling them from the inside. The term, however, is now applied to any type of radiator in which tubes are arranged horizontally so that the air passes through their interior and the water over their exterior surfaces.

Hook (or Hooke's) Joint.—The same as **Universal Joint.**

Horn Block, or Horn Plate.—Horn plates are brackets which act as guides in which the back axle may move up and down on its springs, the horn blocks being made in pairs for this purpose, and the axle moving up and down between the two. Obviously, horn plates prevent free and ad movement of the axle, and so obviate the use of radius rods.

Horse Power.—Power is the unit of measuring capacity of an engine for doing work, since it is necessary to institute comparisons in this direction between various engines. For this purpose the horse power, as founded by James Watt, is still used. In establishing this unit Watt calculated the work that could be performed continuously by the largest dray horses, and to be on the safe side, added 50 per cent. to his estimate.

Accordingly, a horse power is the capacity for doing 33,000 foot lbs. of work in a minute. It does not matter whether 1 lb. is raised 33,000 feet, or 33,000 lbs. are raised 1 foot in a minute; in either case a horse power is expended. Therefore, the total number of foot lbs. of work that an engine can perform in a minute divided by 33,000 is its total horse power.

Housing.—A cavity for the accommodation of a ball, or roller, bearing in the stationary structural part surrounding the shaft to which the bearing is applied.

Hub.—The centre of a wheel; more especially applied to wire wheels.

Hunting.—With some governors, an engine, when free from its load, tends to race round and attains a high speed before ever the governor can come into action. When, however, the governor does act, its action is so pronounced as to slow the engine below the speed for which the governor is set, and it is only after a series of speed oscillations, so to speak, that the engine is set to work at its governed speed. This belated and exaggerated action of the governor is known as "hunting."

Hydrocarbon.—A term used in connection with fuels, which are chemical compounds of carbon and hydrogen.

Hydrometer.—The same as **Densimeter.**

Ignition.—The kindling of the explosive charge in the cylinder, and for practical purposes it is carried out by one or two broad systems. Ignition is either by battery or magneto. In the battery system either accumulators or primary batteries can be used, four volts being the usual pressure at which the primary circuit is worked. In either case this circuit is transformed up by means of a coil, as the igniting spark between the sparking plug points has to occur at a voltage of 4000 or so. (See **Coil**.) Current is made to flow, at the required moment, by the contact maker. (See **Contact Maker**.) The circuit has to be suddenly broken as well as made, to get a good spark at the plug, and so contact makers are made on either one of two principles. Either they may be so designed with a spring to make and break contact very suddenly, or they may depend for the sudden make or break on a trembler on the coil. (See **Trembler**.) In magneto ignition too we have two broad varieties—the low and high tension. In the low tension an armature with only low tension winding is provided, and consequently the circuit has to be broken. As the spark is produced at the point where it is broken, this break has to occur inside the cylinder among the explosive gases. This is effected by a trip tappet mechanism worked from the cam shaft in such a way as to cause the break to occur at the correct moment. In the high tension magneto system the armature is also provided with secondary or high tension windings which enable the magneto directly to give off high tension current that will jump between the poles of an ordinary shaped sparking plug, the timing of the passing of the spark being regulated by a contact breaker fitted to the armature shaft of the magneto, and much on the lines of that used with accumulator ignition.

Incrustation is formed in boilers, radiators and water pipes, owing to the salts that are deposited by any but absolutely pure waters. They are chiefly sulphates and carbonates of lime. A useful remedy to lessen and get rid of such incrustation is ordinary soda.

Indicated Horse-Power.—Horse-power that is actually being expended on the piston by the gases in the cylinder, as distinct from brake horse-power, which see. Measurement of this power can be obtained by an indicator, an instrument which takes diagrammatic readings of the power so that the pressure at any point during the stroke of the piston can be ascertained, and, consequently, the whole of the work being performed in the cylinder can be calculated.

Induced Current.—A current obtained in a circuit by induction from another circuit in the same way as the primary ignition circuit through the coil induces a high tension current in the secondary winding.

Induction Coil.—See **Coil.**

Induction Pipe.—The pipe by which the gases are led from the carburettor to the cylinder.

Induction Valve.—The valve by which the flow of gases from the carburettor to the cylinder is timed

and regulated. It is usually in modern engines operated positively from the cam shaft, but sometimes is still merely a spring loaded valve opened by the suction of the engine.

Injector.—An instrument in which, by utilising the momentum of water when made to move extremely rapidly, the boiler is supplied with water forced into it despite the boiler pressure opposing the supply. To do this steam is passed at high velocity through a series of jets around which the water lies. The paradox of the injector is generally explained by the fact that, when the steam picks up the water and carries it through the injector, it induces a very high speed in that water. Consequently, the water has a lot of momentum which overcomes the pressure of the boiler opposed to its entry.

Inlet Pipe.—See **Induction Pipe**.
Inlet Valve.—See **Induction Valve**.
Inner Tube.—The rubber air tube of a pneumatic tyre.

Inspection Door.—A light metal lid fitting over a hole in a cover, such as a crank case, and easily removable so as to render the mechanism in the interior of the casing available for inspection.

Inspection Lamp.—See **Lamps**.

Insulation.—Is material such as rubber, etc., which will not conduct electricity, and so is wound round electric conductors in order to protect them. Insulation may mean the act of protecting such circuits by insulating material.

Insulating Tape.—A tape made of indiarubber and gutta-percha so that it insulates any electric connections round which it is wound. It is so sticky that the end can be cut off and stuck down to prevent it coming unwound.

Intensity Coil.—See **Coil**.

Internal Combustion Engine.—An engine in which the fuel is consumed directly in the cylinder, and the expansion caused by the burning of that fuel is made to act directly on the piston. The internal combustion engine in motor work may be regarded as the alternative to the steam engine, in which the fuel is used more indirectly (see **Steam Engine**). Internal combustion engines act on one of two principles—either four cycle or two cycle—for which see under these headings.

Iron.—A metal used more than any other in car construction. Known chemically under the symbol of Fe, there are practically two varieties of iron, widely different from each other, the one cast, the other wrought iron, for which see under these respective headings.

Irreversible Steering.—Steering so designed that while the driver, by turning the steering wheel, can turn or swivel the front wheels, the front wheels cannot turn the steering wheel; consequently the car with irreversible steering tends to run on in the direction for which the steering wheel is set. Irreversible steering is usually obtained by a worm on the steering column in mesh with a toothed sector, the rocking lever which moves the rod connecting to the lever arm by which the front wheels are swivelled. The worm is cut at such an angle that, while it can move the sector, the sector cannot rotate the worm. Hence the name.

Isothermal Expansion.—When a gas at a given pressure in a cylinder moves the piston of that cylinder outwards so as to allow the volume of the gas to expand, the pressure of the gas would fall proportionately to the increase of its volume, neglecting the heat lost in work, the consequent fall in temperature, and the losses of condensation, etc. This law of the pressure of a gas varying in inverse proportion to the volume it has to fill is known as Boyle's law. Of course expansion on these lines is only possible in theory; it is known as Isothermal Expansion.

Jack.—An implement for lifting heavy weights, especially cars. Car jacks almost invariably depend for their action on the mechanical advantage obtained from a lever rotating a screw, thus giving a double mechanical advantage. The casing of the jack stands firmly on the ground, and contains a rotatable sleeve which is threaded for the accommodation of the lifting screw. When this sleeve is turned in one direction the lifting screw is worked upwards out of the sleeve, and thus is

lifting action obtained. Sometimes for convenience a ratchet action is employed with the lever for turning the sleeve.

Jackets.—The word generally applies to water jackets surrounding the cylinders of internal combustion engines, but in some steam engines the cylinders are surrounded with steam jackets to maintain the temperature in the cylinder, and thus avoid the power losses that would otherwise be caused by the condensation due to cylinder surfaces not sufficiently warm.

Jet.—The spray nozzle, through which the fuel in an internal combustion engine is delivered from the carburettor to the engine. The word may also be applied to liquid fuel burners employed in steam engines.

Jockey Pulley.—A pulley rotating on a centre, the position of which can be adjusted to requirements by fixing it on one end of a lever arm. A jockey pulley is generally used to take up slack in a belt.

Joint.—Joints are of many sorts, and for many purposes. There is the expansion joint, to permit pipes to expand under heat without causing leakage to the joints; such joints usually obtain their effect by allowing a certain amount of spring action on the pipe. Then there is the flanged joint used for either pipes or shafts, in which the flanges are connected by bolts or studs and nuts. There is the ordinary face joint where the surfaces of metal are screwed together and frequently to render them gas tight are treated with red lead, or have some material like sheet asbestos interposed between them. The union joint applies only to smaller pipes and is formed of the well-known union nut which presses a flange on the pipe against the connection by screwing them on to that connection. A universal joint exclusively applies to rotating shafts, which are required to transmit movement more or less flexibly, while a ball and socket joint is usually found on such parts as steering connections.

Journal.—The part of a shaft running in a bearing.

Key.—A small piece of metal of varying lengths—usually rectangular in section—which is employed to connect moving members such as shafts, etc., to parts such as wheels which have to be rigidly secured thereto. A key ordinarily is fitted in a groove cut on the shaft and into a corresponding groove cut in the boss of the wheel, so that the shaft cannot rotate without the wheel following suit, unless indeed the key were to be sheared in two. Keys usually taper very faintly along their length, so that when driven up they secure the wheel tightly to the shaft.

Key-Seat.—The same as **Key-Way**.

Key-Way.—The groove made for the accommodation of the key.

Knock or Knocking.is a peculiar and unmistakable noise in an engine. Since it is usually caused by the mechanism between the crank and piston, it generally sounds as if it were coming from the cylinders. It may be due to worn bearings, to insufficient or unsuitable mixture in the cylinder, to improper ignition timing, or to overloading in the cylinder. In any case steps should be taken to stop it as soon as possible.

Knuckle Joint.is the joint usually seen on engine control rods, and sometimes on steering rods, radius rods, etc. In a knuckle joint (sometimes called a double eye joint) at one part the knuckle is slotted out so as practically to constitute the fork, between the cheeks of which the other connection is accommodated. A hole passes through this connection and both sides of the fork, and through this hole a bolt, which forms the connection, is passed, the bolt sometimes being locked with a nut on its end, but sometimes with a split pin or other device.

Knurling.—The mechanical roughening of a metal surface, which gives an appearance somewhat similar to the engine turning seen on a watch. Frequently found on the edges of the heads of fine adjustment screws, etc.

Lamps.—The most that can be done is to review the different methods of car lighting at present available. A car in Great Britain has to carry several sorts of lamps. There is the tail lamp, which must illuminate the back number and show a red light behind. In the front, carried on forked brackets, are the head lamps, usually powerful lights. One of these may be carried

on either side of the car, or a large one in the centre, and in addition to this, side lights are also sometimes carried. These are less powerful lamps, generally placed on either side of the front seat of the car. At present there is a tendency to make the head lights swivel with the steering so as always to show the light in the direction in which the car is travelling, and authorities in the motoring world are also endeavouring to arrange that lamps shall be placed as far as possible at the outermost points on the sides so as to indicate to others the width limits of the car. As regards the various forms of illuminating, the most sophisticated undoubtedly is the electric light, generally obtained from a small dynamo worked off the engine in conjunction with accumulators, that can be brought into action when the engine is not at work. There are many forms, however, of electric lighting systems, many of them of the highest ingenuity, but acetylene is another medium, giving, if anything, a more powerful light, and with a completely carried out acetylene instalment only one generator is necessary for all the lamps on a car. Oil lamps and paraffin lighting are hardly sufficient to depend on, but are frequently used for the side or tail lamps, or both. An inspection lamp is another type that every car ought to possess. It should be electric to avoid risk of petrol explosion.

Landaulet.—A car in which the upper back part of the body, which consists of a folded hood, can be opened or closed at will, while the front part remains permanently standing.

Lap.—Lap is a term applied to the side valves of steam engines, and means the amount by which the end of the valve overlaps the outer edge of the corresponding steam port when it is in the middle of its stroke. It must overlap the outside edge of the steam port, and may overlap the inside edge. Sometimes, however, the valve in its middle position not only fails to overlap the outside edge, but leaves an opening along this edge. This is known as negative inside lap. Engines with negative inside lap would be very free running but wasteful. It is the ordinary outside lap that renders possible the expansive working of the steam.

Lateral Thrust is sideways stress.

Lay Shaft.—A lay shaft is in reality an intermediate shaft for transmitting motion through gearing. It is usually applied either to the shaft transmitting movement from the engine crank shaft to the cam shaft when the latter lies along the tops of the cylinders, or it may be the intermediate shaft in the gear box which transmits the motion from the primary shaft to the final drive from the gear box.

Lead is a term used to denote the amount of advance in opening of a valve ahead of the piston before the latter is at the end of its stroke. The word is also applied to any electrical wire.

Lever.—A long handle turning on a pivot or fulcrum and used for many purposes, especially for controlling engine and change speed gear and brakes on a car. Levers have sometimes to be designed to increase the power applied through them in which case the length of the actuating arm is longer than the arm taking the force from the fulcrum to its point of application. These forces vary directly with the length of the arm. Take a lever with the force applied at 2 ft. from the centre of fulcrum and giving off the force again at a point 1 ft. away from the fulcrum, the force given off will be just twice that applied.

Lifter.—See Exhaust Valve Lifter.

Limousine.—A permanently enclosed car.

Limousine—Landaulet.—See Three-Quarter Landaulet.

Liner.—A liner is almost invariably cylindrical and is fitted into cylindrical holes, either to diminish the size of the original hole, or when applied to cylinders and wearing parts, to afford renewed wearing surfaces.

Link.—In car work is a form of connection used for coupling two members together. It may be used to couple up two brake connections, or two levers. A good example of the link is to be seen in the spring hanger swing links, connecting the ends of the link with the spring hangers of the frame. It is also used for the swinging quadrant in steam engine valve gear.

Linking Up.—See Valve Motion.

Link Motion.—See Valve Motion.

Liquid Fuel.—Apart from the liquid fuel in internal combustion engines, fuel is generally used in a liquid form for heating the boilers on steam cars, for which purpose it is more compact than the ordinary coal or coke. It is usually applied either through an injector or spray, or else through a heated coil, whence it issues in the form of vapour, which is ignited at the burner orifice.

Live Axle.—See Axle.

Live Steam.—Steam at pressure, direct from the boiler.

Load may apply either to the actual load carried by the car, or to the resistance put *on* to the engine, against which it has to work.

Lock.—See Steering Lock.

Locking Nut.—Locking devices are used to prevent bolts and nuts from slacking back.

Low Pressure Cylinder.—See Compound Engine.

Lubrication.—The medium used to reduce friction between two surfaces working relatively to each other. For motor work lubricants nearly always take the form of grease or oil, which works in as a film between the surfaces. Lubrication should be chosen to enable this film to be retained under the load on the particular bearings, etc., for which it is used.

Lubrication System.—The system of lubrication of car mechanism, especially of the engine and gears, is all-important. The gears in general are fairly simply lubricated by filling the gear box up to the required amount from time to time. The engine, however, demands more than this, and may be lubricated on the splash system, in which oil is simply supplied to the crank case and all bearings and surfaces depend on the lubricant splashed up by the rapidly rotating cranks as they churn through the oil. In another system oil is carried in a tank above the engine, generally on the dash board, and its flow to the engine is regulated by the amount of pressure in the tank, such pressure being usually obtained either from the exhaust or from a small air pump driven by the engine. The most generally adopted system in modern cars is the force feed in which oil is forced under pressure by a small engine-driven pump (either a gear pump, a rotary or reciprocating pump) to all the bearings and moving parts of the engine that require lubrication. For this purpose very often the crank shaft is made hollow and utilised to conduct the oil to all the crank bearings, and up the connecting rods to the gudgeon pins. Sometimes oil is forced through a gallery tube with little holes in it just opposite the bearings requiring lubrication.

Lubricator.—A device for feeding lubricant to mechanisms. Some are designed so that the amount of oil supplied can be seen passing through sight-feed glasses.

Magnetic Clutch.—A clutch in which the driving and driven parts are connected together by magnetism. They are practically never used except in special designs of electric and petrol electric vehicles.

Magnetic Field.—The space through which the magnetic lines of force, between the poles of a magnet, pass. It might be better described as the field of magnetic influence.

Magnetic Lines of Force.—The forces of attraction between the poles of two magnets are, for convenience, conventionally supposed to follow or to be represented by certain definite lines known as "lines of force," and when a bar of iron, or iron wire, cuts these lines of force it causes an electric current to be set up in the iron.

Magneto.—A compact and specialised form of dynamo fitted on car engines, and so designed that, when driven by the engine, it shall supply electricity for the ignition of the charges in the cylinders, and ensure that the sparking for this purpose is passed between the points of the sparking plug in the cylinder at the right moment.

Main Bearing.—A bearing of the crank shaft.

Make and Break.—The mechanism to regulate the flow of current in the primary circuit in ignition systems that are not fitted with trembler coils.

Manometer.—A pressure gauge.

Mechanical Efficiency.—See Efficiency.

Mechanically Operated Valve.—An inlet valve positively opened and shut by the mechanism of the engine, as opposed to the automatic inlet valve opened merely by the engine suction.

Metal to Metal Clutch.—A clutch in which the contacting surfaces are both of bare metal.

Micrometer.—An instrument for measuring extremely accurately to very small fractions of an inch.

Mild Steel.—See **Steel**.

Mileometer.—An instrument for measuring distance by mileage.

Milled Nut.—A nut the edges of which are formed with serrations similar in appearance to those found on the edge of a shilling. This is done to afford a better grip.

Mis-Fire.—Sometimes owing to the charge of air and vapour momentarily not being in explosive proportions, or because of defective ignition, a charge may enter the cylinder and leave it without being exploded. This is known as a mis-fire. When anything causes mis-firing, these mis-fires are usually intermittent.

Mixing Chamber.—That part of the carburetter in which the fuel and air for the engine are brought together.

Mixture.—The mixture is a combination of air and vapourised or gasified fuel, to be exploded in the cylinder.

M.O.V.—Short for "mechanically operated valve."
Mud Guards.—The protective coverings placed over the wheels of a car to prevent mud being splashed over the vehicle.

Muffler.—Another word for the silencer.

Multiple Disc Clutch or Multiple Plate Clutch.—A form of clutch in which the friction for transmission of power is obtained through frictional contact between two or more plates or discs.

Nail Catcher.—A device, usually consisting of a short length of chain like a curb chain, resting lightly across a pneumatic tyre, from which it extracts nails and such like things as the wheel revolves.

Natural Circulation.—See **Cooling System**.

Naphtha.—A hydrocarbon liquid sometimes used as a fuel for internal combustion engines. Naphtha can be distilled from coal, wood, or crude oil. Its chief drawbacks lie in a tendency to mess up the cylinders, and in the extremely unpleasant smell of the exhaust. It is more generally suited for comparatively slow running engines.

Nave.—The hub of a wooden wheel.
Needle Valve.—The spindle in the float chamber of a carburetter usually ends in a point, which is forced by the action of the float on to a corresponding seating as soon as the petrol reaches a certain level in the float chamber. This is the needle valve. The term can be applied to any very fine pointed small valve.

Negative Pole.—See **Accumulator**.

Nickel (Ni).—Chemically speaking, an elemental metal, at present much used for alloying with steel, to which in certain proportions it gives great strength and toughness, the most usual proportions being up to three or five per cent nickel. For special purposes, as, for instance, valves, however, the proportion of nickel may go as high as 25 per cent. One of the great properties of nickel steel is its capacity to resist what is known to engineers as "fatigue," and what is sometimes erroneously called the tendency for the metal to "crystallise."

Nipple.—The same as jet. (See **Carburetter**.)

Non-Return Valve.—The same as **Check Valve**. See **Valve**.

Non-Skid.—A device applied to tyres to prevent side-slip of vehicle. These, at present, usually consist of bands studded with hardened steel studs which grip the surface of the road, but sometimes mere chains loosely passed round and round the tyre and wheel rim, are used. Many attempts, too, have been made to produce mechanical non-skids as part and parcel of the car mechanism, but hitherto they have not met with much success.

Normal to.—At right-angles to.

Notching-up.—The same as **Linking-up**. See also **Valve Motion**.

Nozzle.—Usually applied to the carburetter jet.

Nut.—The ordinary nut is too well known to need description, but it is found in many varieties besides the usual hexagonal form. There are various forms of hexagonal locking nuts, as for instance, castle locking nuts (see under separate heading), and helicoil nuts (the latter made from coiled steel, so that the coils spring slightly and so bind on the thread). There are also milled and knurled nuts, merely circular, and since they are to be turned only by hand, are made with their circumferential edge rough, so as to afford a grip. The wing nut is another form of hand nut, with wings formed on it to give more power for screwing up; this is sometimes known as the butterfly nut; while the union nut is employed for joining up pipes to their fittings.

Odometer.—An instrument for measuring the distance run.

Offset.—Ordinarily the centre line of a cylinder, if produced, would fall dead on to a line drawn through the centre of the crank shaft, but when cylinders are placed so that their centre line is parallel but somewhat to the side of this line, they are said to be *offset* or *décalé*. With this arrangement there is no dead centre.

Oil Gauge.—A device by which the level of oil in a tank can be shown. It may be in the form of a glass tube on the same principle as a water gauge of a boiler, or it may be arranged to show the level by means of a needle on a dial.

Oil Pump.—See **Lubrication System**.

Oldham Coupling.—A form of flexible shaft coupling in which the end of each shaft to be connected is formed with a flange, each having a groove, like that of a key-way, right across its face. Interposed between these two flanges is a floating disc with projecting tongues at each side to fit into the grooves on the flange faces, but these projecting tongues are arranged so that the one on the one side lies at right-angles to that on the other side. Thus, while allowing the floating coupling to move in one plane relatively to the driving shaft, it allows the driving shaft to move in another plane, at right-angles to that allowed to the coupling itself. The driven shaft can thus move in two dimensions, similarly to a universally jointed shaft.

Otto Cycle.—See **Four Cycle Engine**.

Overheating.—When the supply of lubrication is insufficient to counteract the friction in a bearing, or between quickly moving or heavily loaded surfaces, the friction generates heat, and if the action continues, this overheating may cause serious damage by the metal becoming abraded and particles consequently working in between the moving parts and cutting them. Lack of lubrication also causes overheating of pistons in engines, but engines may also overheat owing to causes arising from the combustion of the fuel, as for instance improper mixture, or defective water circulation.

Packing.—The word packing may refer to thin strips of metal placed underneath a bearing or any part to raise it to the required height, or it may refer to the relatively soft material inserted between the two metal surfaces of a face joint, or the word may be applied to the material put into glands to render them steam or fluid tight. For face joints, red lead, or rubber and canvas insertion, are frequently employed, and sometimes corrugated plates of thin soft sheet metal, while for glands, either soft metallic packing enclosing the rod and spindle, or hemp saturated with tallow or grease, may be used.

Packing Ring.—A piston ring is a packing ring, but the principle may be applied equally well to cylindrical sliding valves.

Panne.—**En Panne.**—A term borrowed from the French, meaning a break down of the car. In English we say "huig up."

Paraffin is sometimes used as a fuel for steam engine driven cars and sometimes for internal combustion engines, in which latter case the fuel should be split up into as small particles as possible and vapourised or heated.

Parallel.—When all the positive poles of the cells in a battery are connected up to one side of the circuit, and all the negative poles to the other, the battery is

said to be connected up "in parallel," as opposed to being connected "in series." (See *Series*.)

Pawl.—A pawl may be likened to a door which will permit rotary motion to pass only in one direction. It is used in connection with a ratchet. The pawl, which is merely a catch, is hinged on the driving member that is rotated in one direction, and it falls, or is pressed by a spring, down on to the faces of the teeth of the circular ratchet, which transmit the movement to the driven member. If the pawl tends to rotate faster than the ratchet (in the same direction) it catches against the saw-shaped ratchet teeth, and driving pawl and driven ratchet revolve as one. If, however, the pawl is rotating more slowly than the ratchet, or is moving in the opposite direction, the ratchet, owing to the saw-like shape of its teeth, overruns the pawl, which merely drags along over the tooth faces without connecting driving and driven members. One of the best examples of a ratchet and pawl mechanism is seen in the free wheel of a bicycle.

Pedal.—In car work a pedal is that part of a control mechanism on which the foot is placed to operate it, but it is now usually applied to the entire lever when operated by foot. They are used for operating the brakes, clutches, accelerators, and on some cars for gear change economy. Some motor cycles are fitted with pedals similar to those on ordinary cycles, to be used in starting the machine by pedalling it along.

Pest Gook.—Small tap used to indicate the level of water in a boiler.

Petrol.—The spirit most generally used for motor work. It is a comparatively light hydrocarbon distillate of mineral oil, ranging in weight from about 6.8 to 7.6 lbs. to the gallon (680 to 760 sp. g.). Needless to say it is highly inflammable and therefore stringent by-laws regulate the storage of it in any quantity. In America it is called gasoline, in France, *essence*. As it is very volatile at ordinary temperatures, it mixes easily with air, so as to form an explosive mixture for internal combustion engines.

Phetion.—An ordinary open touring car.

Pinion.—A word applied to the smaller of any two gear wheels that are in mesh together.

Pins.—Pins are of many sorts, and apart from cases in which the word has been applied to important parts of the mechanism, as for instance a gudgeon and crank pin, it generally implies some sort of fastening or means of securing a fastening, the most general examples being cotter pins which are tapered pins used for locking nuts, or, similar connections held in position with a nut. A taper pin is very similar to a cotter pin, but depends upon its taper fitting to remain in position, since it has no securing medium. Then there are split pins which are passed through holes, and while the head of the pin prevents it moving in one direction the other end that is split is splayed apart to prevent it from falling out of the hole in the other direction.

Pipe Union.—See *Joints and Nuts*.

Piston.—A piston is really a plunger fitting pressure tightly, but a sliding fit, in the cylinder to transmit the working pressure of the gas in the cylinder to a connecting rod. As its motion is purely reciprocating, the connecting rod translates the reciprocating movement of its one end into the rotary movement of the crank at its other end. In double acting engines, such as steam engines the piston is a metal disc (with its circumference grooved for the accommodation of the packing rings), formed at its centre with a boss in which the piston rod end is secured, but in internal combustion and other single acting engines no piston rod is necessary, and consequently the piston is made somewhat in the shape of an inverted bucket, the top transmitting the pressure, while the walls accommodate gas tight packing rings, and the inside, underneath the top, accommodates the gudgeon pin, enabling the connecting rod to be secured directly to the piston.

Piston Ring.—A split metal ring fitting in grooves in the piston, and so proportioned as to spring upwards against the walls of the cylinder or barrel so as to ensure that the piston or plunger shall be a gas tight but sliding fit.

Piston Rod.—The rod connecting the piston with the cross-head, and so indirectly with the connecting rod. It is practically only used in double acting engines.

Piston Speed.—The speed at which the piston travels along the walls of the cylinder is calculated in feet per minute. It is found by multiplying the length of the stroke by twice the number of revolutions per minute of the engine (twice, because the piston makes two strokes—one up and one down—to each revolution of the engine). Formerly 1000 ft. per minute was regarded as the maximum permissible piston speed, but now the tendency is towards far higher speeds in internal combustion engines, in fact over 4,000 feet per minute has been known, for it appears that the limiting factor of such speeds is the number of reversals of stress—first in one, then in the opposite direction—that can take place in the time, rather than the mere rubbing speed between piston and wall.

Piston Valve.—See *Valve*.

Pitch.—When several holes are drilled at regular intervals in, say, a plate, the distance from the centre of one hole to the centre of the next is the pitch. The same word also applies to the distance made by the thread of a screw in a single turn. In gear wheels the pitch may be calculated on the circular or diametral bases, for which see *Circular Pitch* and *Diametral Pitch*.

Pitch Circle.—When two gear wheels are in mesh, there is a plane passing exactly midway between the roots of the teeth of one wheel and the roots of those on the other, and if circles were drawn from the centre of both wheels so as to touch this plane, the circles would themselves just touch each other. These circles show the mean diameter for gear calculating purposes.

Pitting.Is the uneven wearing away of surfaces, nearly always due to corrosion. It is most noticeable on the seating of valves, for here a very little makes a difference, and here it shows itself in tiny hollows and depressions on the surfaces of the seatings. It is due to corrosion from the gases passing over the seating.

Pivot.—The centre on which a lever rotates or oscillates. The same as fulcrum.

Plain Bearings.—Bearings offering sliding contact, as opposed to bearings that depend on rollers contact, like ball or roller bearings.

Planetary Gear.—See *Epi-cyclic Gear*.

Plate.—This word has a fairly wide application. It may be applied to the lead plates or grids in accumulators, to angle plates used in the construction of car frames, to baffle plates, to flitch plates on frames, to friction plates in clutches, or to number or identification plates; or, again, in cab or public service vehicles, to license plates.

Plate Clutch.—A clutch depending for its action on friction applied to the surface of plates. These plates are usually secured to both driving and driven parts of the clutch, and are so arranged that those on the driving can be slid into contact, as required, with those on the driven shaft. The plates are often made of sheet metal if many are used in a clutch.

Platinum.—A rare and extremely refractory metal under heat; consequently it is much used for contact makers and tremblers at the point where the circuit is made and broken and where it is subjected to the great heat of the spark. A great deal depends on keeping the surface of these platins clean and level, to ensure that they give good contact.

Platinum Tipped Screws.—See *Contact and Platinum*.

Plug. (See *Sparking Plug*).—The word is also used for the wash-out plugs in boilers of steam wagons.

Plunger Pump.—A pump from which fluid is forcibly delivered by the action of a plunger working in a barrel into which the fluid is drawn through a non-return inlet valve.

Pneumatic Tyre.—See *Tyres*.

Poppet Valve.—The same as a mushroom valve, a name given it on account of its shape. This is the usual type of valve used on the internal combustion engines of cars. The lower side of the mushroom head, all round near the circumference, fits on the seating, and may be flat or bevelled according to the shape of the seating.

Popping.—When the inlet valve does not close quickly enough before the explosion the beginning of the explosion may tend to escape through the still open

inlet valve, in which case part of the explosion passes through the inlet pipe to the carburettor, causing a "popping" noise in the carburettor.

Port.—A passage formed in the body of the part to which it belongs. More especially applied to the inlet and exhaust passages in cylinders.

Port Bar.—The strip of metal dividing one port from its neighbour. Usually in steam engines.

Port Faces.—The surface in the steam chest through which the opening of the ports occur.

Positive Action.—Action obtained through the medium of solid mechanism. When a valve is lifted bodily by a solid cam bearing against it, it is said to be positively operated—but not if lifted by spring action or suction.

Potential.—Potential may be regarded as the sort of level of electric pressure, and therefore "difference in potential" means "voltage."

Power.—The capacity for doing work. (See **Horse Power**.)

Pre-ignition.—When from any cause ignition occurs too early in the cylinder, it produces an unpleasant knock in the engine, sometimes even stopping it, owing to the explosion occurring too early and tending to drive the piston downwards when it is on its upward stroke, while the engine running in a given direction. Pre-ignition is usually caused by over-heating, which in turn is frequently due to a deposit of burnt carbon on the walls of the cylinder and combustion chamber, such deposit resulting from excess of oil in the cylinder having been burnt and deposited on the walls in the shape of carbon.

Pressure Feed.—See **Feed**.

Primary Battery.—A battery capable of itself generating electric current, as opposed to an accumulator, which is only a medium for storing electricity.

Primary Circuit.—The low tension circuit in an ignition system.

Primary Shaft.—The driving shaft in a gearbox.

Propeller Shaft.—The shaft by which the engine power is transmitted from the gear-box to the live back axle, or to the counter shaft driving the road wheels. Since at its one end the gear-box is secured to the frame which moves up and down on its springs, and at the other the shaft connects with the axle that is supported directly on the road surface without the intervention of springs, there is a tendency for the front end to move up and down relatively to the other. Therefore, owing to the constantly varying angle at which the propeller shaft on a live axle car has to work, universal joints are provided at one or both ends. If only at the front end, provision is made for a slight sliding movement at the other end, as the distance between the driving bevel and the front end of the shaft must vary somewhat with the varying angle of the shaft.

Pusher.—A small wheel designed to drive or be rotated by either flat, V section, or round types of belt for light work, as, for example, in motor-cycle transmission, or for the driving of cooling fans, etc., in car work.

Pump.—In car work pumps are used for the supply of fluid, either water or oil, to the parts requiring it. Broadly speaking, they may be classified as reciprocating and rotary pumps, the reciprocating being of the plunger type (See **Plunger Pump**); while the rotary include centrifugal and the gear pump, for which see under their respective headings. For steam wagons and cars a pump is usually of the plunger variety, and in large wagons sometimes worked directly by a little steam cylinder connected with it. Pumps are also used for the supply of air pressure to tyres or to the oil or petrol tanks. In the latter case they may be driven from the engine, or where exhaust pressure is used, be merely hand pumps to obtain sufficient pressure to start the engine, after which the engine provides the pressure.

Quadrant.—For practical purposes a quadrant in automobile nomenclature means the metal arc which frequently forms the combined rack and index for the operation of control levers, and for holding them in any required position.

Racing of Engine.—Allowing the engine to run over-fast. It sometimes happens when the engine is run-

ning with the clutch out, but engines can be over-driven with the clutch in and the vehicle moving.

Rack.—The word usually given to the serrated quadrant along which the control levers are regulated, the serrations of which hold the levers in any position desired.

Radiator.—An appliance for cooling the circulating water which in being passed through the radiator is split up so as to afford as much contact as possible to the cooling surfaces of the radiator, which obtain their cooling effect from the air.

Radius Rod.—A rod by which the back axle is anchored or held in place more or less in a longitudinal direction, and which also transmits the thrust from the driving wheels to the frame of the car, thus ensuring that the frame and body of the car move with the wheels.

Ratchet.—A wheel with teeth cut in a particular way so as to engage with a pawl only in one direction of motion, and in the other to overrun the pawl. (See **Pawl**.)

Registration.—By law every vehicle running on roads in Great Britain has to be registered and carry an identification number, assigned to it on paying the registration fee.

Regulator.—The throttle. Usually applied to steam cars, in which the word is also applied to the device which governs the amount of air pressure to the burner.

Resistance.—A device to oppose the flow of electrical current. Resistances are usually made variable, and thus can be used as a means of regulating the flow of electrical current. As a resistance in the circuit results in the production of heat, such resistances may also be for warming apparatus, etc.

Retard.—When the timing variation of the spark in the cylinder is so placed as to cause the spark to take place late in the engine cycle of events, it is said to be retarded. With a spark fully retarded, the piston is somewhere on its way along its working stroke before ignition, and consequently explosion takes place.

Reverse Gear.—The mechanism for enabling the car to travel backwards. If a driving gear wheel is rotating in a clockwise direction, the driven shaft will revolve in an anti-clockwise direction, but if the drive be transmitted with an intermediate gear interposed between the driving and the driven shaft, the latter will rotate in a clockwise direction—exactly the opposite to what it did when in direct gear with the driving shaft. It is on this principle—by the introduction of a third gear—that the reverse is obtained in the gear box of a petrol car, and in some steam cars, though, in general, backward movement of the steam car is obtained by reversing the engine through the medium of the valve motion.

Rheostat.—Another name for an electrical resistance.

Rim.—The metal ring or band of flanged section steel that surrounds a wheel and accommodates the tyre. Many of these rims are now made detachable, so that when a tyre failure occurs, the tyre and rim can easily be removed bodily from the wheel, and substituted by another tyre and rim.

Ring Lubrication.—Some bearings, which are designed with a trough of oil underneath but not touching the journal, are provided with flat metal rings hanging from the shaft and dipping into the oil. The rotation of the shaft journal causes the rings to revolve, and thus oil gets carried on to the journal.

Rings.—See **Packing Ring** and **Piston Ring**.

Rivet.—A metal pin connection usually employed for joining metal plates together. The rivet is formed with a head on one side, and is forced through the holes in the plates. The projecting end is then hammered until it also is formed into a head, and between the two heads the plates are tightly gripped. The heads may vary widely in shape. Rivetting may be done either hot or cold. In the former case, the rivet is cooling tends to contract and grip the plates very tightly.

Rocking.—See **Rocking Lever**.

Rocking Lever.—A rocking lever is a lever made with a shaft as a fulcrum, and around this shaft it

oscillates, or, if made in one with the shaft, it oscillates with the shaft in bearings around the latter.

Roller Bearings.—Are bearings in which the sliding action of the ordinary plain bearing is supplanted by the rolling action of rollers, in a way exactly similar to that of ball bearings, but whereas each ball gives little more than a point of contact, every roller affords a contact line of appreciable breadth.

Roller Chain.—In a block chain the metal blocks that come in between the teeth of the chain wheel, when working, involve a more or less sliding contact against the surfaces of the chain wheel teeth. To overcome this, the roller chain has been introduced. In this, hardened steel rollers capable of easy rotation on steel bushes are substituted for the blocks, and the teeth of the chain wheel are modified accordingly. Thus the working contact between the chain and the teeth is one of rolling, not sliding contact.

Rotary Pump.—A pump in which the fluid is pumped by rotary action.

Rotary Valve.—A type of valve of which we may see more in the future. It is usually employed for regulating the supply and escape of gases for the cylinder, and this is effected by revolving in a cylindrical chamber in which ports are cast. As the valve itself also has ports which register for those in the chamber at the proper moments, it is enabled by its rotation to regulate the passage of gases to and from the cylinder.

Rubber Tyres.—Solid rubber tyres as opposed to pneumatics are used largely on industrial vehicles of all sorts, especially on the heavier types. It is worth noting that vehicles above 2 tons in weight, if fitted with rubber tyres, are still allowed a speed of 22 miles an hour, which is considerably more than that permitted with hard tyres. The law here makes a practical difference between rubber and metal tyres.

Runabout.—A small type of car generally intended for light touring work.

Safety Valve.—A fitting applied to boilers to enable superfluous steam to be discharged as soon as the pressure exceeds a certain working maximum, at which the valve is set. This setting is obtained in the case of motor vehicles by calibrated springs which hold the valve on its seating until the maximum boiler pressure is reached.

Saloon Limousine.—A limousine in which all the seats are enclosed.

Saturated Steam.—Steam that is not superheated. (See **Superheated Steam**.)

Screen.—A glass protection placed in front of the driver, and usually nowadays so devised as to be put at any required angle. Wind screens are often made in two pieces, each of which can be set at any angle to the other. They are also sometimes employed to protect the occupants of the back seats of a car from the weather.

Screw.—A screw is too well known to need description, but it may be pointed out that its principle is absolutely only that of the inclined plane or wedge, following a circular path instead of a straight one. There are various sorts of screws, as, for example, the adjusting screw (the purpose of which is obvious from its name); counter-sunk head screw, which has its head fitted in a counter-sunk recess so as to leave it flush with the surface; the cone screw, the grub screw, the set screw, and many others.

Screw Thread.—The thread of a screw is the outstanding part in the shape of a coil, which fits into a correspondingly shaped helical recess in the hole that accommodates the screw. Into this it threads.

Scuttle Dash.—A term applied to the type of dash board which more or less merges into the bonnet at the front, and in being carried backward practically follows the lines of the car body.

Seating.—See **Valve Seating**.

Secondary Battery.—An accumulator.

Secondary Circuit.—High tension circuit.

Sectional Tyre.—See **Block Tyre**.

Selector.—The word is sometimes applied in the same sense as the word "quadrant," but at other times, as when used of a reversible steering gear, it is really a section of a gear wheel acting as a lever with teeth suitably cut.

Seize.—When a piston or bearing is overheated

from any cause, so that it binds tightly in its cylinder or bearings, it is said to have seized.

Selector.—In modern change speed gear each change in speed is generally obtained by sliding one or other pair of gears into mesh with each other, each separate slide being effected by its own separate fork. The sliding guide or selector rods, which usually lie horizontally, are slotted at their outer ends, and these slots are so arranged as to lie in a line, and thus the selector (worked by the driver from the change speed lever) is free to slide into the slot in any required rod as desired. Sometimes the selector rods are substituted by levers which have slotted or forked ends.

Self Starter.—A device for turning the engine crankshaft to start the engine, instead of by the usual crank handle. Engine starters may be either mechanical, using the stored energy of a spring compressed by foot; they may depend upon compressed air admitted to the engine cylinders, or to the cylinders of a little subsidiary starting engine (usually with a pinion on its shaft in mesh with the gear ring on the engine fly-wheel), or they may be electrically worked, in which case they usually also act through a pinion in mesh with a gear ring on the fly-wheel circumference. For power, they depend on accumulators, and consequently the electric starter is often combined with the electric light equipment of the car.

Series.—When a battery is connected up with the positive pole of one to the negative pole of the next cell and so on, the battery is said to be connected up in series, as opposed to being connected in parallel.

Series Wound.—Electricity is produced if an iron bar be passed between the poles of a magnet. The stronger the magnet the more work has to be done in passing the bar between the poles, and the more electricity is produced. Magnets are of two sorts, permanent or electro magnets, and the latter, which are much the stronger, depend on a current of electricity being passed along an insulated circuit or winding passing round and round them. When this winding is made part and parcel of the main circuit of the dynamo, the machine is known as a series wound dynamo.

Set Screw.—See **Screw**.

Shackle.—A shackle is a double link joint like the connection of a spring to the frame.

Shaft.—There are many types of shaft in motor work. There is the cam shaft (see under that heading) driven from the crank shaft, which in turn drives the shaft upon which the clutch is mounted—the clutch shaft. This occasionally is the one with the primary shaft in the gear box, whence the power is taken through gears to the secondary shaft or lay shaft. On leaving the gear box it may be carried either to the counter-shaft, which lies across the frame of the car and is provided with a balance gear (to enable the power to be transmitted by side chains to the rear wheels), or the propeller shaft—otherwise known as the cardan shaft—may take the drive to the shafts of the rear live axle, which latter are usually connected up by the casing of the balance gear.

Shaft.—See **Eccentric**.

Shock Absorber.—A device usually of the dash pot variety (See **Dash Pot**) to deaden the action of the axle springs in their recoil. It is most desirable that the springs should act over road inequalities as quickly as possible, but it is also most desirable that they should return to their position quietly.

Short Circuit.—When a current of electricity, instead of traversing the entire circuit intended, leaks at some point and so returns by a short cut, it is called a "short circuit," or "short" for brevity. The terminal may become loose, touch the frame and short circuit the current, or the wire may fray and a strand touch part of the frame or engine. Or, again, a short circuit may be caused by rain falling on the sparking plug and acting as a path for the electricity. Short circuits usually show themselves by irregular misfiring in the cylinder affected thereby, but sometimes one gets intermittent shorts, which is evidenced only by occasional fits of misfiring and again, or by a solitary misfire at considerable intervals.

Shunt.—A shunt is a loop line, as it were, from off the main electric circuit. One most generally comes across it in connection with the term "shunt-wound."

Shunt Wound.—When the windings round the poles of the magnets in a dynamo consist of a shunt from the main circuit, the dynamo is said to be shunt wound. (See **Series Wound**.)

Side Slip.—This takes place when the tendency to sideways movement of the car is greater than the adhesion of the wheels on the road surface. Consequently it takes place on slippery surfaces, and can be counteracted to a considerable extent by roughening the surface of the tyre to enable it to obtain a better grip on the road, also by careful braking.

Sight Feed.—A device generally used in conjunction with lubricants to show that the supply of oil is being duly passed to the engine and bearings. It usually takes the form of a glass tube. As it is let into the pipe line, as it were, one can see the oil passing to its destination drop by drop. Sight feeds are often provided with fine adjustment for regulating the oil flow.

Silencer.—The metal box into which the exhaust gases from the engine are passed and expanded before going out into the atmosphere. Some silencers merely depend for their silencing action on allowing the gases to expand in them, so that they can then take their own time more or less in flowing out into the air, while others depend upon baffling them, while others combine both these systems.

Silent Chain.—The more correct term for the silent chains that have recently come into so much favour is "inverted tooth chains." In these chains the links are made up of metal plates, shaped at each end with tooth projections facing inwards towards the centre of the chain wheel when in action. These toothed plate links are threaded on steel bushings or rockers which minimise friction, and are so arranged that they alternate in direction; that is to say, if one plate stretches to the right, that next to it stretches to the left, and these plates being similar at both ends, the same arrangement occurs at each end of the links, and so on until the chain is completed. Now as these links swing on their bushings, or rockers, with any movement of the chain, they adjust themselves to the pull of the chain or to the surfaces on which they bear; thus when wear occurs to the chain wheel they are, by this facility of self-adjustment, to some extent independent of any consequent loss of pitch.

Single Cabriolet.—A cabriolet with no light or window in the quarter behind the door.

Single Landulet.—A landulet with no light or window in the quarter behind the door.

Skew Gear.—Skew gear is an arrangement of spur wheels in mesh with each other, the spur wheels having their teeth cut diagonally across the face of the wheel circumference, so that each tooth comes gradually into engagement with its companion tooth on the other wheel instead of coming suddenly into action all along its length, as in the case of the ordinary straight-cut teeth of gears. If the teeth are cut at a sufficiently acute angle across the face of the circumference, or the circumference face is sufficiently broad, each tooth amounts to a screw thread.

Skid.—Another word for side-slip.

Sleeve.—A casing, usually surrounding a shaft and generally capable of sliding along that shaft. The best examples of sleeves are found in gear boxes.

Sleeve Valve.—Besides the ordinary steam slide valve, which is well known, recent years have brought us slide valves for internal combustion engines, and the best known of these is the system in which the valves constitute sliding liners in the cylinder and surrounding the piston. These valves are made to slide up and down, and are formed with ports cut in them in such positions that at the right moments in the valve movement these ports register with passages, permitting the inlet or escape of gas, as the case may be. Slide valves may also be arranged to work in separate chambers. (See **Valve**.)

Slip.—Sometimes when a clutch is put in very violently and the surface of the road is slippery the driving wheels momentarily revolve without biting the road; they are then said to be slipping. The word is also used loosely for side-slip. When the friction in a clutch is from any cause inefficient and the surfaces of the driven member do not grip, conditions also result in what is known as "slipping of the clutch." Sometimes

in changing gear it is desirable to slip one's clutch slightly, and this can be done by almost taking it out of engagement, or holding it in very light engagement.

Snug.—A small projection sometimes fitted on bolts to prevent their turning round in their holes.

Soap Stone.—An insulating material at one time considerably used to form the bearing upon which the rocking shaft for the igniter passed through the walls of the cylinder in low tension systems of magneto ignition.

Socket.—See **Ball and Socket**.

Solder.—A mixture of 66 parts of lead to 34 of tin used for joining metals together where no particular strength is required, but where an easy and quick process is desirable. A flux is necessary in connection with this process, the flux varying with the metal to be joined up. Spirits of salt, "killed" by dissolving as much zinc therein as the spirits will hold in solution, is used for soldering iron and brass; sal ammoniac for copper; but when iron is soldered it must first be tinned. In any case absolute freedom from dirt and grease is necessary where the solder is to be applied. Only quite a moderate temperature is required.

Soldering Bit or Soldering Iron.—Somewhat of a misnomer, as it is usually of copper, of sufficient mass to hold a considerable amount of heat for soldering purposes.

Soldering Lamp.—The blow-lamp used for soldering.

Solution.—A word usually applied to rubber in more or less liquid form. It was formerly much used for applying patches, but for this it has been generally superseded by the vulcanising process. It consists of pure rubber dissolved in spirits.

Sooting.—The deposit of carbon in the cylinder, owing to impurities such as too much oil, etc. Its presence is particularly felt when the sooting is deposited on the sparking plug and affects the regularity of the firing.

Sparking Plug.—A sparking plug is the device by which the electric current for the ignition is carried from the outside to the inside of the cylinder (leaving the latter gas-tight) and also affords the point at which the spark is produced. Ordinary sparking plugs afford a connection for the high tension wire at its outside end, where a central insulated wire carries the current to the inside of the cylinder. The insulation is unusually very thick and very refractory under heat, for with the continuous explosions in the cylinder the sparking plug becomes extremely hot. The insulating material is held in a metal body which screws into the cylinder metal, making with the aid of a copper and asbestos washer on the face of the metal a gas-tight joint, and, as the heat to which the plug is subjected causes expansion of the insulation, provision also has to be made for this in the design of the sparking plug.

Spark Timing Variation.—At its full speed the internal combustion engine is running so fast that the crank pin and piston have travelled quite an appreciable distance in the interval between the passing of the spark and the time that the explosion begins to take full effect. Consequently, at high speeds the spark should occur in the cylinder earlier in the cycle of engine events than at slow speeds. Now the contact maker is practically made up of two main parts, the one rotating with the cam-shaft, the other fixed. If, therefore, the fixed part can be made so that it can be rocked slightly in order that the fixed and rotating parts make the contact earlier or later as required in the revolution of the engine, this variable timing will have been achieved, and this is exactly how it is effected.

Specific Gravity is the basis of relative weight. We take the weight of water as the standard unit, calling it 1, and if a good bulk of any substance weighs half as much as the same bulk of water, then its specific gravity will be half (0.5), if a quarter, 0.25, and so on.

Speed.—In the United Kingdom cars are restricted by law to a maximum speed of twenty miles an hour for cars up to two tons in weight. Above that weight up to five tons, twelve miles per hour has to be observed if the tyres are of rubber or soft material, whilst, if of hard material, eight miles per hour is

permitted to vehicles of from two to three tons weight unladen, and five miles per hour for three to five-ton cars. All vehicles hauling trailers are restricted to five miles per hour.

Speedometer.—An instrument for measuring, and often for recording, the speed of a car. It should preferably be worked from the propeller shaft, as the back wheels may give a certain amount of slip, and the front wheels are objectionable for the purpose owing to the necessity for them to swivel.

Spigot.—When the end of one pipe fits inside the beginning of another pipe, as in ordinary water mains, etc., it is called a spigot joint, and when one shaft at its end is hollowed out to provide accommodation for a bearing in which the end of another shaft shall rotate in alignment with it, it is called a spigot bearing. Spigot bearings are often found in gear boxes between the driving and driven ends of the divided gear box shaft.

Spiral Gear.—A misnomer frequently used for skew or helical gear.

Spiral Spring.—A spring the shape of the main spring of a watch.

Splash Lubrication.—See Lubrication.

Split Pin.—See Pin.

Sprag.—A device for preventing a car from running backwards down hill. In the older designs of cars the sprag was a stout steel rod that could be let down at will so as to dig into the road if the car ran backwards, but nowadays a ratchet mechanism is more generally favoured, in which a pawl can be let down at will on to the teeth of a ratchet, which latter, if the car attempts to run backwards, is prevented by the pawl from rotating backwards, and thus any movement is stopped.

Spraying Chamber.—The same as the mixing chamber of a carburettor.

Spring.—Springs are of many sorts. Firstly, there are springs for supporting the frame and carriage on the axles. These may represent a single arc of a circle, in which case they are called half elliptic springs, or there may be two half elliptics opposed to each other and meeting in a knuckle joint at each end; they are then called full elliptic springs, while, if instead of a dumb iron a short spring of approximately the same shape as the dumb iron is substituted therefor and connected with a half elliptic spring the result is a three-quarter elliptic spring. See springs are so called from their similarity to the letter "C," the body being suspended from the upper end of the C. For carriage suspension and mechanism helical, volute, and spiral springs may be used, the volute spring being like a helical spring, the coils towards one end becoming smaller and smaller in diameter. This form of spring has much to recommend it for some purposes, for the larger coils are the first to deflect and it is only as the load increases that the smaller coils come into action; thus a well graduated effect is obtained. The term spiral spring is often used to denote a helical spring, but it should in reality be confined to those springs similar in shape to the mainspring of a watch. Helical and volute springs of round section steel are most generally employed for the important purpose of bringing the valves back to their seatings after the cam or engine suction has lifted them.

Spring Drive.—In some cars the power from the engine, instead of being transmitted through more or less rigid mechanism to the wheels of the car, is taken up by interposing springs which somewhat reduce the shock of any sudden application of power. This, it is claimed, prolongs the life of the tyres.

Spring Washer.—A washer designed so as to exercise a spring effect on the nut or bolt to which it is fitted, so that the nut is pressed hard against the sides of the thread and so prevented from working loose.

Spur Gear.—Wheels for this purpose are known to a good many as cog wheels.

Staggered.—Spokes are said to be staggered when they are alternately sloped or inclined in opposite directions to each other, the one tending to lean over from right to left, its neighbour from left to right and so on.

Starter.—See Self Starter.

Stauffer Lubricator.—The caps fitted to bearings for the supply of grease. The tops of these caps are made so that they can be screwed down and so squeeze the grease into the bearing.

Stay.—A member used to hold or steady any one part of construction relatively to another part. The word should be confined to those staying members only that are in tension. See Strut.

Steam Chest.—The sort of box, attached to the cylinder, in which the slide valve works.

Steam Engine.—See Engine.

Steam Pump.—See Pump.

Steel.—A metal widely used in motor car construction owing to its strength. Ordinary steel is iron chemically combined with carbon which has a hardening effect, but as the proportion of carbon is only a matter of degree, steels vary enormously, from mild steel, which is practically little more than wrought iron and is comparatively soft and tough, to high carbon steels used for tools which are extremely hard, and though possessed of great strength have not the toughness of the milder metal (see **Crucible Steel**). This last sometimes is called cast steel, but there is also another form of steel which is cast in much the same way as iron to obtain complicated shapes. To differentiate, it is most convenient to call this last material steel casting as opposed to cast, crucible, or tool steel. Such steel castings are different in their nature from iron castings, being much tougher and capable of being bent. Tool steel is made by melting down comparatively high carbon blister steel in a crucible. Mild steels are usually made by the Bessemer or Siemens process, the latter being more general. Between the mild and high carbon steels is an infinite range of carbon contents with consequent variety of strengths and elasticities.

Steel Castings.—See Steel.

Steering Column.—The hollow column carrying the steering wheel at its top, and incidentally also generally accommodating the levers for operating the engine.

Steering Connecting Rod.—The rod connecting the lever arm on one of the steering rod wheels with the lever operated by the movement of the steering wheel on top of the column.

Steering Coupling Rod.—The rod connecting the lever arms on each of the two steered rod wheels.

Steering Gear.—The mechanism used for directing the car as required. For lighter cars it is practically invariably of the Ackermann type with the centre part of the axle rigidly secured to the springs and only the stub ends of the axle, secured to the centre part by enlarged and exceeding strong knuckle joints, capable of movement. In the theoretically correct steering gear a line prolonged through the centre of the axis of the pivot on which the steering axle swings should coincide at the ground with the vertical axis of the wheel (see also **Irreversible Steering**). In many heavy steam wagons and tractors the whole front axle pivots on a centre pin, movement around this centre being controlled by the driver through chains wound round a drum so that when the chain on the one side is slack the chain to the other side of the axle is correspondingly tightened.

Steering Lock.—The maximum angular amount that the front or steered wheels can swivel round from side to side. It is sometimes indicated by the minimum circle in which the vehicle can turn.

Steering Wheel.—The wheel at the top of the steering column, by the rotation of which the driver controls the direction of the car.

Stop Valve.—A screw down valve for shutting off steam supply.

Strainer.—See Filter.

Striker.—A name sometimes given to the selector arm or lever. Also the arm of the rocking lever through which in many valve systems, the valve is actuated from the cam. The word also applies in low tension magneto ignition to the arm of the rocking lever which breaks the contact inside the cylinder.

Striking Fork.—The forked lever or rod that slides the gears in or out of action.

Striking Rod.—The same as a selector rod.

Stroke.—The full travel of the piston. It equals the diameter of the circle described by the crank pin. The ratio between stroke and bore is one of great importance in engine design. Of late years the tendency has been to make the stroke longer and longer relatively to the bore, and this has certainly led to an extremely efficient engine.

Strut.—A constructional member used to hold and steady one part of a construction relatively to another. The word, however, should only be applied to those steadying members that are in compression. (See **Stay**.)

Stub Axle.—The short swivelling axle on which each steering-goad wheel runs.

Stud.—A headless bolt screwed into a casting or main construction and left with a considerable length projecting, this length being screwed. The part secured by the studs is drilled so that it can be passed over the stud, and nuts screwed on to the projecting ends of the studs, holds it in place.

Stuffing Box.—See **Gland**.

Sub Frame.—See **Under Frame**.

Surface Carburettor.—See **Carburettor**.

Suspension.—Generally the supporting of the frame and body on the axles. In automobiles this is invariably carried out through springs, which may be arranged to support the frame either at three or four points. The three point suspension was at one time greatly in vogue, but is now not so widely used. The word is also used to designate the manner of securing engines or gear boxes to the car frames. As it is impossible to make a frame absolutely rigid some makers secure these details to their frames at three points only to allow the frame its inevitable "whip" without unduly stressing gear box or engine. This three point suspension is, however, only used for engines up to a moderate size.

Sulphating.—The action that takes place in the plates of an accumulator when ill-used or neglected. It is evidenced by white, either in spots or in a film on the plates. In such case the accumulators should be run out, and any loose pieces removed, then filled with fresh acid solution and charged at a low rate until the plates resume their normal appearance.

Sump.—A word in the bottom of the crank case.

Superheated Steam.—Ordinary steam at any given pressure has its corresponding temperature, and if the steam falls below this temperature, condensation begins; consequently pressure falls. If therefore such steam does any work, that work absorbs heat, the temperature drops, the pressure falls and a certain amount of condensation takes place leading to further losses. To avoid this, it is possible to impart to the steam a surplus amount of heat, raising its temperature to considerably above the normal point. Such steam in working has a margin of heat in hand and will not condense as easily as ordinary saturated steam. It is therefore more economical if the additional heat can be supplied economically.

Superheater.—A device for superheating the steam, sometimes found in the smoke box of large capacity boilers on road vehicles.

Tail Light.—A light that has to be carried by law on machines in this country at night, and lighted with the other lamps, within an hour after sunset. It must be so arranged as to illuminate the back number plate, and also to show a red light at the back.

Tappet.—The mechanism conveying to the valve spindle the movement imparted by the rotation of the cam. It is usually a plunger rod, with a roller bearing on the cam surface, and is generally made of adjustable length so as to leave as little space as necessary between its face and the bottom of the valve spindle. It works in tubular guides made as long as possible, and a good deal of the quiet running of the engine depends on the tappet design. Many are fitted with springs inside so as to come into contact more gently with the bottom of the valve spindle, and where the latter comes in contact are frequently provided with fibre surfaces to reduce noise.

Tare.—The weight of a vehicle when empty. It really represents the non-profitable but unavoidable load.

Tension is a direct pulling stress.—The words also apply to what we may call electric pressure, in other words, voltage.

Terminals.—The metal attachments fitted to the end of electrical wires to connect them.

Testing.—The verification of the correctness of every adjustment in a car. Also to a lesser extent the determination as to whether any of the material used is faulty. In manufacturing, testing usually is divided into engine testing and chassis testing. The engine when assembled is bolted to a stand and run some hours under its own power and slowly. This is known as "running in" and smooths down the lesser inequalities of the bearings, pistons and cylinders. Then the fly wheel is coupled to any convenient mechanism for absorbing a measurable amount of power. This may consist of a dynamo, the electrical output from which can be measured, a frictional brake in which the power absorbed is measured by springs or weights, an air brake (in which a fan is used that is known from previous determinations to absorb a given amount of power when driven at a particular speed), or, lastly, an hydraulic brake may be used, though this is unusual. The horse power developed at different speeds is then measured to see if it is satisfactory, and should it not be so adjustments will be made until it is considered right. Often there is then a run of several hours under full power, this being intended, if possible, to develop any weakness which may be latent in the engine but undiscovered during the "running in." Then when the engine is in the chassis and the latter has been fitted with a rough body a road run is taken to see whether the other parts of the car perform properly, whether all the control levers work smoothly and without difficulty and whether the gears are reasonably quiet in action, whether the steering is as free and accurate as it should be, and so on. This road test, of course, also is liable to develop latent weaknesses due to bad material. Usually considerable adjustment is made during the road test to one part and another and the manufacturer commonly employs quite a small staff of experienced men who take every car for a short road run to pass it before it leaves the factory.

Thermal Efficiency.—The thermal efficiency of an engine or system is the proportion of the total amount of work got out of it compared to the total amount of work put into it as represented by the thermal value of the fuel put into it. For instance, suppose an engine burning 1 lb. of coal per minute develops 33 horse-power, and the value of the coal represents 14,000 British Thermal Units (nearly 11,000,000 foot pounds of work, or nearly 330 horse power) the thermal efficiency is 10 per cent.

Thermo-Dynamics.—Heat and work are mutually convertible. The work done by a brake block in retarding a vehicle generates heat which may leave the brake block almost red hot; on the other hand, the heat in a fire box is, through the medium of expanding steam, converted into work by the engine. These are only two familiar examples of a universal law. But we know the exact quantity at which heat and work can be exchanged; 772 foot pounds of work will generate sufficient heat to raise one pound of water 1° F. temperature. This capacity to make a pound of water one degree is taken as the unit of thermo-dynamics, and is known as the British Thermal Unit, otherwise B.T.U. Now a horse-power represents the capacity for doing 33,000 foot pounds of work in a minute; therefore the capacity to impart about 43 B.T.U.'s per minute represents the equivalent of a horse-power. If all the heat in a pound of coal could be used up it would amount to about 14,000 B.T.U., and a single pound of coal represents the capacity for doing nearly 11,000,000 foot pounds of work, and if burnt in one minute, nearly 330 horse-power.

Thermo-Syphon.—See **Cooling System**.

Thread.—See **Screw-Thread**.

Three-Quarter Cabriolet.—A cabriolet with a window in each quarter behind the doors.

Three-Quarter Landaulet.—A landauet with a window in each quarter behind the doors. Sometimes called a limousine-landauet.

Three-Quarter Limousine.—A limousine with a window in each quarter behind the doors.

Throttle, or Throttle Valve.—The regulator

of an engine. It is usually either a flap rotated on its axis, and so in one position blocking the pipe while in the extreme opposite position it only presents its edge to the inflowing gases, or it may be a piston sliding in a tubular passage, longitudinally or rotatorily, and uncovering ports therein as required.

Thrust.—Some shafts are subjected to a force acting along their length, as, for instance, is usually the case with the clutch shaft. This is known as thrust.

Timing.—This word is applied either to the ignition of the valve mechanism. As regards ignition, see **Spark Timing Variation.**—The timing of valves differs on different engines. As a rough general rule the exhaust valve should begin to open when the crank pin is at about 45 degrees from its bottom dead centre, and should shut over the top stroke, while the inlet valve should open just after the exhaust valve has shut and should close at the bottom of the stroke. By drawing full sized a diagram of the circle described by the crank pin, the position of the piston in the cylinder at any of these points can be obtained, and by inserting a wire spoke through the compression cock in the top of the cylinder the piston position can be shown from outside. Then by altering the timing of the gear wheels driving the cam shaft the valves can be arranged to lift at the right moment.

Toggle Joint.—A toggle joint is a device used where considerable power is required, as, for instance, in applying brake shoes to their drum surfaces. It consists of two short and strong rods hinged together at one end. In the case of brake blocks the outer ends connect one to each block. The toggle links are at an angle to each other, and when the power is applied it tends to force them into a straight line. The result is that the ends tend to move further apart and are moved outwards with great force, thus pressing the brake shoes against the drum. The whole principle depends on straightening out two links originally at an angle to each other.

Tool Steel.—The same as crucible steel, and capable of being tempered and rendered very hard. —See **Steel.**

Torque.—This is the turning effort on the shaft or rotating part. It is a factor in which the distance at which the force is applied from the centre—in other words, the leverage—is an important influence; in fact, torque is made up by the turning force applied, and the distance at which it is applied from the centre of rotation.

Torque Rod.—In a live axle there is a tendency for the drive to twist the axle round with the driving shaft, in the direction of the latter's rotation; that is to say, to whirl the axle transversely around across the car, like the hands of a clock. To avoid this, torque rods are fitted. Usually they are led through the top and bottom of the balance gear casing to a pivot of one of the cross members, a spring being frequently employed to ease the stresses.

Torque Tube.—Sometimes, instead of a rod, a neat tube encasing the propeller shaft is employed, although to call it torque tube is generally somewhat of a misnomer, for the ordinary torque tube, although it acts as a distance piece similarly to a radius rod, does not usually do much to counteract torque.

Touring Car.—A term generally denoting a car with an open body, usually fitted with a cape cart hood.

Tractive Resistance.—The resistance which the road wheels of cars experience from the surface of the road. The tractive resistance for solid tyres is about 3 per cent. more than that for pneumatics. As the diameter of the wheel increases so the resistance decreases, and up to certain limits the resistance also decreases with increase of breadth of tread.

Trembler.—The device used for breaking the circuit. With contact makers of the make and break type (see **Contact Maker**), the trembler is the contact maker, but with wipe contacts the trembler is placed on the coil where its action is as follows:—When the wipe makes contact, the current passes in the coil and magnetises the core. The trembler is then pulled down against the core and so breaks the circuit. When the circuit breaks, the core ceases to be magnetic; the trembler then springs away from the core, and by making contact joins the circuit up

again with the result that the core is again magnetised, and the whole process repeated. All this happens tremendously rapidly so that the coil in breaking from contact to core and back again, does so so quickly as to emit a continuous buzz, the note of which affords a gauge of the efficiency of the trembler's working. When working well, the trembler should emit a fairly high note.

Trip Rod.—The rod in certain forms of low tension magneto ignition, by which the movement of a cam is transmitted to the rocking lever inside the cylinder so as to move the lever and by thus breaking the circuit to cause a spark.

Trunnion.—A Journal secured to a part to enable it to be swung or oscillated on the centre of that journal.

Tube Ignition.—In the early days of the automobile, the charge from the cylinder was exploded, in most cars, by means of a tube kept red hot by a lamp placed at the side of the cylinder. To resist the heat these tubes were of platinum, and consequently very expensive. Tube ignition is now obsolete.

Tuning Up.—Adjusting a car, more or less by trial and error in running it, so as to get the best possible results on the road.

Turn Buckle.—A device for tightening up wires or any thin diameter rods that are merely acting in tension, as, for example, the brake pull rods. Into each end one of the halves of the rod is screwed, but a right hand screw is used for one, and a left hand screw for the other, rotating the turn buckle in one direction forces them apart, whilst if the other it pulls them together, and so tightens them as required.

Two-Cycle Engine.—In a two-stroke engine an explosion occurs in each cylinder once for every revolution of the crank shaft; consequently the engine cannot have a suction and compression stroke, as in the four cycle type. In this engine compression usually in part takes place in the crank chamber, or by a separate compression pump, and as the piston is forced down by the explosion the exhaust port is uncovered by the piston, while almost immediately after the inlet connecting the crank chamber with the cylinder above the piston is uncovered. A baffle plate, however, prevents the inflowing gases from reaching the exhaust port at first, and before any serious loss could take place, the exhaust port is covered up by the piston moving on its up stroke.

Two to One Gear.—The same as **Distribution Gear.**

Two Way Cock.—A cock or tap enabling fluid passing through it to be made to flow in either of two directions at will, or to shut it off entirely.

Tyre.—One of the most important features of motoring. Rubber tyres are pneumatic or solid, but in some cases, on heavy utility vehicles, iron or steel tyres are used. In the heavy vehicle class, the speed may depend on the sort of tyre usually the rubber tyre is fitted to any vehicle up to the final weight limit of five tons, it may run at the maximum twelve miles an hour, whilst if steel or very hard tyres are used, the speed has to be kept down to five miles per hour, for vehicles of three to five tons unladen weight, and eight miles for machines of from two to three tons weight unladen. On heavy wagons and lorries, if fitted with strokes the latter must comply with the regulations as to distance apart, &c.—Amongst the solid rubber tyres there is a considerable variety: there are single and twin tyres, the latter for heavy loads on back wheels (twins are seldom used on front wheels). Then there are the sectional, or block tyres (see under that heading), and others in which the tyre consists merely of a series of rubber section pads projecting through the steel of the rim.—The pneumatic tyre is composed of an inner tube with valve, which latter when in position passes through the felloe of the wheel, and the outer cover which is of rubber and fabric thickened at the edges so as to form a beading fitting into corresponding grooves in the rim of the wheel. The arrangement of the beading is such that the pressure of the tyre tends to hold it in position in the rim, and the higher the pressure, the tighter the tyre holds. The fabric is introduced into these outer covers particularly for protection, but partly to render

them inextensible. The inner tube is usually only of rubber, and would stretch to bursting point when pumped up, if not restricted within the outer casing. In fact, if there is a large hole in the outer casing there is a risk of the inner tube bursting through this. To guard against such contingencies of late years some inner tubes are reinforced with fabric all along the outer part of their circumference, so that whilst the fabric does not prevent their being fully blown up, it prevents the tube being stretched beyond a given degree.

Under-Frame.—A small sub-frame placed in between the main longitudinals, and usually carrying the engine and gear-box, but sometimes only taking one of these details.

Under-Shield.—A sheet metal protection, in some cars made in one with the metal from which the frames are hydraulically pressed, to guard the engine and gear-box from underneath against stones, mud, and wet from the road.

Union.—See Joint.

Universal Joint.—A joint to impart flexibility to a rotating shaft. It is, in fact, a double-angle joint, similar in principle to gimballs of a compass. The shaft is connected to a pin in such a way that it can swing around the pin in one plane—say in a plane, for the moment, horizontally transverse to the car—whilst the pin itself is free to turn in a vertical plane at right angles to the other. Thus the shaft is doubly jointed to allow it to swing sideways, both right and left, and up and down—in fact, in any direction required. An important point about a theoretically perfect universal joint is that the axes of these two joint pins should lie in the same vertical plane.

Valve.—There are many kinds of valve. Valves in general are for regulating the flow of fluid, whether liquid or gaseous, the simplest being the non-return or check valve, which is simply on the principle of a door, only opening one way, and so only allowing flow in one direction. Such valves are usually pushed open when the pressure exceeds a certain amount, and shut down on their seating as soon as any fluid tends to flow back. They may be adjusted to open at a given pressure either by making them of a certain weight or by controlling them with a spring. There are several sorts of these valves. The flap valve actually is a door, only opening one way. Then there is the ball valve, frequently falling back on to its seating by its own weight, and the mushroom valve, either working by weight or by a spring. The name is most frequently given, however, to the valves which regulate the supply of gases to the engine, enabling it to work. In an internal combustion engine they are usually of the poppet type, lifted at the required moment by cam action, and returned to their seating (which is either conical or flat) by a spring. For inlet valves, however, the automatic type is still sometimes used. It is provided with a much weaker spring, to enable the valve to be opened by the suction of the engine. Of late years, slide and piston valves have also been introduced in internal combustion engines. The slide valves are usually made to slide up and down between the cylinder walls and the piston, by eccentric rods working off the distribution shaft in such a way as to uncover inlet and exhaust ports at the required moment, the ports or passages being shaped so as to maintain the opening for the required interval. Piston valves (which are nothing more than pistons uncovering passages at the required moments), are also worked in the same manner in some engines, the pistons sliding in their chambers. Then there are rotary valves, which continually revolve in one direction, and at the correct time allow passages cast in them to register with passages in the cylinder so that the gases flow into the cylinder or escape out of it as required.—In steam engine practice we get rather different kinds of valves, the usual being the "D" valve, made to slide on flat surfaces in which are passages for the flow of the steam, the valve regulating the supply and exhaust at the required moment. In some steam engines piston valves are employed, the idea in this case being merely an elaboration of the "D" valve, for the piston valve is made round with passages formed in it to give the required openings to inlet and exhaust at the correct times and for the

correct intervals. The ordinary "D" valve is exposed to the full pressure of the steam, and has to work with this full pressure upon it. It is, however, sometimes balanced or made to press against faces on both sides to avoid this. The piston valve has the pressure equally all round it and at both ends, so that it is self-neutralised, or balanced, and from this point of view is preferable to the "D" valve.

Valve Face.—That part of a valve which comes in contact with the seating and which does the actual cutting off of the supply of fluid. Usually applied to "D" valves in steam engines. It virtually corresponds to the seating of poppet valves.

Valve Chamber.—The cavity in which the valve is placed; usually applied to internal combustion engines.

Valve Chest.—The kind of box in which the valve of a steam engine works, and from whence it distributes the steam to the cylinder. Also called the steam chest.

Valve Lift.—A term applied to mushroom valves to indicate the maximum amount by which they are raised from their seating when at work. With round valves this lift multiplied by the circumference represents the maximum opening given by the valve.

Valve Motion.—This term is usually applied to steam engines to designate mechanism actuating the slide valves for distributing steam to the cylinders.

The most simple means of doing this is by a single eccentric and rod so placed on the crank shaft as to give the valve correct timing. Such an arrangement does not allow the engine to be reversed unless the eccentric sheaf (see **Eccentric**) is made so that its angular position on the crank can be altered, to enable it to be regulated into a position suitable for the engine when running in reverse direction. Such an arrangement is known as a "shifting eccentric."

The ordinary reversing valve motion, commonly known as the "Stephenson link motion," is provided with two eccentrics and rods, the one affording full forward motion, the other full reverse motion. The rods at their ends are connected to a quadrant shaped link, which is connected with the valve spindle in such a way that the link can be moved so as to bring either one or other eccentric rod directly into line with the valve spindle, in which case that particular rod is exerting its full influence. Suppose the quadrant link is positioned so that the reverse eccentric rod is in line with the valve spindle: the engine is then in full reverse gear. Now if the link is raised so as to take the reverse rod more and more out of line with the valve spindle, and the forward eccentric rod more and more into line with the valve spindle, the influence of the reverse becomes less and less, and that of the forward gear more and more. When in full reverse steam was not being cut off in the cylinder until near the end of the stroke, but as the link is "notched up," as it is called, and the reverse actuating rod left less and less in action, the cut-off of steam takes place earlier, thus permitting more expansive working of the steam. When the link is moved, so that the valve spindle end is at a point on it midway between the two rods, the engine is said to be in mid-gear, and steam is then being cut off at the very beginning of the stroke—in other words, the engine gets no steam at all. From midstroke as the gear is shifted towards full "forward" motion, the cut-off becomes later and later in the stroke until in full forward gear it is being cut-off only when about three-quarters of the entire stroke has been completed. This will serve to explain the rather difficult problem of the ordinary link motion. The only other motion at all largely used is Joy's motion, in which the valve is actuated by a series of links, moving a slipper block up and down in a steel guide. The valve spindle is connected to this slipper block and the guide is so shaped as to give the requisite motion, the reverse being obtained by swinging the guides round to an opposite angle. For instance, if in forward gear the bottom corner of the guide is at 45° behind the top corner, in reverse the guide will be swung on its trunnion so that the top corner comes about 45° behind the bottom corner.

Valve Rod corresponds in steam practice to valve spindle.

Valve Seating.—The part with which the face of the valve is in working contact when shut.

Valve Spindle.—The stem of the valve.

Vaporiser.—A device to reduce liquid to a vapour. In internal combustion engines, the vaporiser is usually used for the less volatile fuels, such as paraffin, in which case it usually depends for its action on heat, often in conjunction with some device for mechanically splitting the fuel up into very small particles. In oil-fired steam engines, it is also applied to that part of the burner which beats up the liquid fuel into vapour or gas before it emerges from the burner.

Variable Expansion.—See **Expansive Working.**

Volts.—A word imported from the French, meaning a small car, generally a two-seater.

Volt.—The unit of electro-motive force, or electric pressure, as it may be called. It is the E.M.F. that will cause a current of one ampere to flow in a circuit having a resistance of one ohm.

Voltmeter.—An instrument for measuring voltage.

Volts Springs.—See **Springe.**

Vulcanising.—The process of vulcanising has revolutionised tyre repair. Raw rubber, which is very plastic and has little elasticity, could not be used alone for tyres: it has to be mixed with other ingredients, more especially sulphur, and subjected to great heat and pressure. The process of vulcanising for a repair consists of applying this plastic rubber and sulphur in correct proportions to the tyre, and subjecting it to suitable heat and pressure. Many of the convenient vulcanisers at present supplied can be carried on a car.

Vulcanite.—An insulating material used in the electrical equipment of a car.

Washer.—A suitably shaped piece of material placed between the two faces of a joint. For the ordinary nut joint a washer is a flat metal ring placed between the nut and the part against which the nut presses; it, to some extent, prevents the nut from working round. Locking washers, which entirely prevent this, are also made so as to hold the nut against the sides of its thread by their spring action. Sometimes, where great heat has to be encountered, and a gas-tight joint has to be made, the washers are of asbestos wrapped in a ring of sheet copper, while for union pipe joints leather washers are frequently employed to render the joint airtight. For electrical work, when required, washers are made of fibre or mica for insulating reasons. For flanged joints, sheet copper or sheet asbestos may be used, the latter especially where heat has to be encountered.

Water Circulation.—See **Circulation.**

Water Jacket.—A chamber formed round an engine cylinder to contain the water for cooling the cylinder.

Watt.—The electrical unit of energy obtained by multiplying the current by the pressure at which the current works—in other words, volts by amperes. It represents a certain amount of electrical energy, which means the capacity for doing work. In fact 750 Watts are equivalent to a horse power.

Welding.—The process of heating two metals until they are in a plastic state, and then with the help of a flux, used to prevent the formation of oxide, hammering the two plastic parts together so that they join and become a homogeneous mass.

Wet Steam.—See **Saturated Steam.**

Wheel.—Wheels are of many sorts. For private car work the wooden artillery wheel with metal hub, the wire spoke wheel, and the pressed steel wheel (similar in appearance to the artillery wheel) are those mostly used. In the wire wheel, the weight of the hub is taken by the tension or pull on the wire spokes from

the upper half of the wheel rim; in the more solid spoked wheels it is taken by the lower spokes in compression. To facilitate tyre repairs, wheels are now often made with rims that with the pneumatic tyres are quickly and easily detachable. For heavy utility motors wheels are made much heavier, usually of wood, though nowadays frequently of steel castings, while for steam wagons and tractors they are often built up of strips of metal plate and T section iron secured to a cast-iron hub. As regards wheels, fly wheels, see under respective headings. Oak and ash are the woods usually employed for these heavy lorry wheels when wood is used, while hickory is generally adopted for the lighter artillery wheels of the private car. There are signs, however, that the supply of this wood (which comes from America) is not what it was, and it is becoming increasingly difficult to get hickory of the best quality.

White Metal.—Is Babbitt or any kindred soft white metal used for lining bearings.

Wick Carburettor.—A carburettor of the surface type in which petrol in a tank is drawn upwards by a capillary attraction so as to saturate a series of wicks, over which the air supplied to the engine is passed. In passing over these wicks the air takes up the necessary amount of petrol vapour.

Wing Nut.—Same as Butterfly Nut. (See **Nut.**)

Wings.—A word sometimes applied to the sides of front wheel mudguards.

Wipe Contact Maker.—A species of contact maker in which the contact is made by a brush or spring-held contact coming smoothly into contact with a metal sector on the insulated circle of the contact maker. As such an arrangement allows for no sharp break of the spark, the break is obtained from a trembler, fitted on every coil using this system of contact making.

Wiper.—A brush, or spring contact bearing, on a wipe contact maker.

Worm Drive or Worm Gearing.—A modification, or elaboration, of helical gearing. In this the smaller gear wheel is represented by a shaft with one or more worms, or threads, cut on it, often at such an angle as practically to constitute a skew gear, the teeth or thread of which meshes with teeth on the larger gear. And here we find the real point of difference from ordinary skew gearing, for the circumference of the larger gear, or worm wheel, instead of being flat as in skew gear, is made concave to shroud the worm pinion. Generally speaking, the best angle at which the thread of the worm should lie along the shaft is 45°, but anywhere between 20° and 45° it can be rotated by the worm when running down hill with the engine shut off. At the present time worm gearing is being very extensively adopted for the final drive transmission, between the propeller shaft and the balance gear of the back axle. It is generally speaking quieter than a bevel drive, though the latter is probably just slightly more efficient, at least when new.

Worm and Segment.—See **Irreversible Steering.**

Wrist Pin.—Another name for the gudgeon pin.

Wrought Iron.—Iron that can be forged. It is made from the harder varieties of cast iron puddled and worked up under the hammer. It is far less liable to unforeseen and sudden fracture than cast iron or cast steel.

Yoke.—Practically a clamp, the ends of which hold down the parts that have to be secured, while the pressure is usually applied by a nut working on a stud or bolt passing through the centre of the yoke. The most familiar application of the yoke is seen in the arrangements for holding the pipes or the valve chamber caps to the cylinder castings, although it is not as frequently used as formerly.

PEARS' DICTIONARY
OF DOMESTIC PETS.

BY THE EDITOR AND EXPERTS OF
The Bazaar, Exchange, and Mart. 975

Pears' Dictionary of Domestic Pets .

INTRODUCTION.

By the Editor and Experts of
"THE BAZAAR, EXCHANGE AND MART."

Comprehended under the popular designation of "pets" is a fairly large number of animals differing markedly in structure, habits, and as regards their general environment, and not a little in respect of their popularity. It is attempted here to consider in as concise and practical a manner as possible the various units composing this divergent group, and to give sufficient information concerning each one discussed as will enable anyone not merely to identify any individual, but also to keep it in health or to treat it when afflicted with at any rate the minor ailments to which it is subject.

Some of the principal families are made up of so many individuals, and the details connected with their successful management are so numerous, that only the very briefest survey is possible in the space at our disposal. Especially is this the case with the dogs and the cats, while even more restricted is the information on rabbits, caviés (guinea-pigs), mice, and rats, all of which are popular with pet-keepers. Then, too, there are others, which, if less popular—monkeys, dormice, and squirrels, for example—need great care and a special environment if their lives are to be pleasant and if they are to afford real enjoyment to those responsible for their well-being.

Though the enumeration foreshadowed may be said to embrace the most popular of all the animals kept purely as "pets," so elastic is the term that it is practically impossible to define its extent. Thus it is necessary so to widen the field of our survey as to take in the strictly utilitarian goat, the smaller reptiles like the lizards, and the tortoises; these last being still more briefly touched upon.

We commence with the dogs, and continue with the other subjects in the order of their enumeration. Still, even with the dogs we do not treat of all the varieties met with in domesticity, but rather with a selection of those which in our opinion are best entitled to be regarded as "pets," for it is possible, we know, to make a pet of any dog whether giant or pigmy. Breeds like Foxhounds, Pointers, Setters, Retrievers, the majority of the Spaniels, and a few other varieties are not included. The whole of the Terrier group (notwithstanding the fact that they are mainly classed as sporting dogs) are dealt with, except the Bull Terrier, Bedlington Terrier, and the Sealyham, whose mission—at any rate for the present—is strictly confined to the realms of sport.

VARIETIES OF DOGS.

Aberdeen Terrier.—An erroneous name often applied to untypical representatives of the Scottish Terrier. The origin of the prefix cannot be traced, but there is not, nor has there ever been, a terrier peculiar to Aberdeen city. (See **Scottish Terrier**.)

Alredale Terrier.—With the exception of the Bull Terrier this is the largest of the group. Though this dog is too big for the work of a terrier proper, it makes a splendid guard, companion, and defender of person or property. Game it certainly is, but its disposition is of the best, and the Terrier is readily controlled; while it is hardy to a degree and one of the best water-dogs. In colour it is an admixture of black or dark grizzle and tan, with a hard, wiry, straight and close-lying coat. A peculiarity of the

breed is that puppies when born are more like Black and Tan Terriers. An Alredale Terrier weighs 40 lb. to 45 lb., bitches being slightly lighter than dogs. The tail is docked about one-half.

Black and Tan Terrier.—A Terrier at one time fairly numerous, but now correspondingly scarce. It is a sleek-coated animal, having excellent claims to be considered a first-rate house-dog and ratter. Not so hardy as some terrier breeds, it is best kept indoors. For town life it is well suited as its coat does not readily show dirt, and it will thrive with a minimum of exercise if judiciously fed. For the coat to possess the glossy appearance liked, regular grooming must be given, and hand-rubbing, using just a suspicion of oil in the palm, should complete the operation. A nicely proportioned dog, weighing from 26 lb. to 30 lb., and sometimes described as the Manchester Terrier.

Black and Tan Terrier (Miniature).—A pocket edition of the Black and Tan Terrier, and the smaller it is the better. There is, however, a difficulty in producing typical specimens. Many are round instead of flat skulled, and the ears often are carried "pricked." Another difficulty is a deficiency of coat in this smart little dog. When this is the case a little lanolin rubbed in after the daily brush has a beneficial effect. Smart, active, and small, this terrier is a favourite in flat-land. Occasionally it "sports" in colour, liver and tans and blue and tans being found.

Bobtail Sheepdog.—By nature a worker this picturesque and essentially English dog has gradually become a fashionable beauty, kept largely as a pet and companion dog. In intelligence the variety is second to none, as it is in docility and strong attachment to its owner. On account of its long, shaggy jacket, however, it is not a general favourite with housewives, though if a long-handled brush be kept where it with to wash it down on wet days, and care is afterwards taken to dry it thoroughly before allowing it indoors, little trouble should be given. We have kept the dogs for many years and they have always proved splendid house-guards and devoted companions. Despite its bear-like gait (when viewed behind) and general appearance it is a most active dog, galloping very fast. Any shade of grey, grizzle, blue, or blue-mixed with or without markings are liked; while in the greyish or blue dogs a pearl, wall, or china eye is a characteristic. The Bobtail is a strongly made muscular dog, standing 22 inches and upwards, with a profuse shaggy outer coat and a waterproof undercoat. Though popularly believed to be born tailless, in nine cases out of ten the tail is removed during the first week of puppyhood—an operation that mutilates somewhat against the more extended keeping of the dog.

Borzoi or Russian Wolfhound.—This hound is the most beautiful and symmetrical of the Great Greyhound group and a very popular dog with both men and women. Though big it is not bulky, and like the Scottish Deerhound and the Irish Wolfhound it will curl up into a comparatively small space indoors, an obvious advantage. As its name unmistakably proclaims, this hound in its native country is used against the wolf, and a brace will render an excellent account of themselves against that formidable animal. Alike as a companion and personal guard the Borzoi may be recommended, while it is no mean watchdog, though it cannot be classed as a noisy variety. Boasting an excellent temperament and a dignified demeanour generally, the dog may be taken out without fear of ill consequences once it has been trained. With this breed as with the Deerhound and the Irish Wolfhound it is best to start with puppies six months old or even rather more, as when young nearly all the Greyhounds seem to be somewhat susceptible to distemper and other ills, but they soon outgrow this if properly fed and housed. Damp is the great enemy; cold they can endure with impunity. Being light-coloured this hound needs to be washed occasionally and to be brushed and combed daily, the tail and feathering requiring extra attention. In height a male Borzoi should measure from girth upwards, and a female two inches less. The skull should be flat and narrow and the head generally so fine that the shape and direction of the bones and principal veins are clearly visible; while viewed in profile it should appear as if Roman-nosed. Generally the dog is built on Greyhound lines. White is the prevailing colour, with or without fawn, lemon, grey, brindle, blue or black markings. Occasionally self-colours are met with. Light-eyed, short-headed, heavy-eared and heavy-shouldered specimens are to be avoided; as are also those having eyes wide apart, or that are barrel-ribbed or cow-hocked. On no account should this variety be chained to a kennel, or a misshapen, broken-spirited animal will undoubtedly result. Care too must be taken in regard to any punishment inflicted on a puppy, as no breed of dog is more sensitive or more readily spoiled by harsh treatment.

Bouledogue Français.—(See Foreign Dogs.) **Bulldog.**—At one time employed in the sport of bull-baiting, the bulldog is now kept as a fashionable canine beauty. It is undoubtedly an ugly dog, but its

disposition altogether belies its appearance. The head is very massive and the face extremely short, with a broad blunt muzzle inclined upwards. Altogether it combines strength and determination with activity. In general the Bulldog may be regarded as well-mannered, and though it makes a good personal guard, in the house its value is not great. Contrary to the opinion usually entertained in regard to the dog it must be classed as delicate. About 50 lb. is the weight of the best specimens, and the hindquarters are always lighter than the forequarters, with a distinct arch of the back. The coat is smooth and fine in texture, and variable as to colour. Whole colours and smuts are most esteemed—brindles, red, white with their varieties, as whole fawns, fallows, etc., while the pied and mixed colours stand next in order of merit.

Bulldog (Miniature).—Even more in favour as a pet is the miniature edition of the larger animal, described above. Formerly this dog was not bred very true to type, it having been tainted with a cross of the French Bulldog; but this has now been altered, and a typical miniature Bulldog is a small edition of its larger relative. This dog should go to scale at 30 lb. or less.

Calpa Terrier.—(See Skye Terrier.) **Chow Chow.**—Thus, the subtle dog of the East, enigmatised, and deservedly, a great reputation as a pet. Though decidedly "stand-offish" to strangers, to its master or mistress it is a most devoted companion, and has a wide and increasing following; while as a house dog it has few superiors. It is one of the prick-eared varieties, and has a flat and broad skull, black tongue and mouth-roof, short and straight back, and a tail carried well over the back. There are two kinds of coat—rough and smooth. The former is preferable, and is coarse, straight, and rather coarse in texture, with a soft and woolly undercoat. In the neck vicinity it is prolonged into a frill. For this reason a collar is undesirable, but if one is necessary it should be of the round or rein type. Black and red are the most favoured colours, though yellow, blue, and white specimens are found. The weight of a Chow Chow is from 40 lb. to 50 lb.

Clydesdale Terrier.—A breed of many names, it having been known as Silkie, Paisley, and Glasgow Terrier, as well as the one now given. Judge by its coat and general appearance the breed is evidently a near relative of the Skye Terrier. It is, however, smaller, silkier as to jacket, higher on the leg, more compact as to body, and more heavily feathered or ear. Kept under natural conditions the coat of this dog should not develop to such an extent as to make the animal a nuisance when kept as a house pet; while its constitution should be improved. The coat in colour is bright steel blue and golden tan, the latter being restricted to the head, legs, and feet; while the tail is deep blue or black. The Clydesdale Terrier is an active and alert dog, and is deserving of extended patronage.

Collie.—So far as the general public is concerned there are two distinct varieties—the rough and the smooth; but fanciers acknowledge a third—the Bearded Collie, a modified Old English Sheepdog that is allowed to possess the whole of its tail. All are most intelligent dogs, and make the finest of companions, house dogs, and protectors. It is frequently asserted that Collies are treacherous, but this is a libel on the breed generally. The rough is more popular than the smooth, but its coat requires far more labour to keep it in nice trim. No collars should be worn by Collies; as this tends to spoil the coat, especially the frill of the rough variety. Sable and white and black, tan and white are the colours most liked, but the blue marle (marbled) is rapidly making headway. A Collie should scale from 45 lb. to 55 lb., and should measure at shoulder 24 in. to 26 in.

Dachshund.—In its native country this dog, as its name suggests, is used against the badger. Here it is but a fashionable pet with a very large circle of admirers despite *Punch's* description. It is a long, low dog with a long and narrow skull showing a decided "peak," short and strong forelegs and higher and lighter-boned hindlegs, a deep chest with prominent breast-bone, and a muscular, arched loin. Colour is of minor import,

but black and tan, liver, liver and tan, red, and dappled are preferred. A typical Dachshund stands from 7 in. to 9 in. at shoulder, and weighs from 15 lb. to 25 lb., and there are both rough and smooth haired specimens. As house dogs and pets the variety may be recommended, being alike alert and intelligent to a degree.

Dandie Dimont Terrier.—Prior to the issue of Sir Walter Scott's *Guy Mannering*, this long-bodied, low-legged terrier was a dog valued purely for its "varmint" qualities. Since shows have popularised it a change has come over the scene, and Dandie has, according to sportsmen, degenerated into a pet. For all that it is a distinctive Terrier with its donned forehead and top-knotted skull, full, round, wide apart eyes, muscular neck, arched loin, short crisp-feeling coat, and short jaily earned tail. Pepper and mustard are the two colours by which the breed is differentiated, and these vary considerably. About 18 lb. is the average weight of the best Dandie Dimont Terriers; while at shoulder they should measure from 8 in. to 10 in. They are hardy, plucky, but not self-willed dogs, most capable guards, and splendid companions. Puppies when whelped differ materially in colour from adults. Peppers are black at birth, or perhaps black with tan legs, while mustards are tan colour with much black down the back.

Foreign Dogs.—Of the breeds falling under the designation of pet dogs, and classed by the Kennel Club as foreign, the chief are the *Bouledogue Français* and the *Samoyede*. The former is an active, intelligent dog, cobby of build, muscular, and heavy as to bone. The skull is massive with a square and massive forehead, large eyes, deep stoop (indentation between the eyes), small neat bat (upright) ears, and short, broad, upturned muzzle. Though on distinct Bulldog lines the variety has not the exaggerated front of its English relative, and is altogether more active and terrier like. Its weight is in the vicinity of 20 lb. Black and black and tan are not admissible as colours for this variety.

The *Samoyede* is a breed that has come rapidly to the front. It is one of the Northern varieties, and a relative, therefore, of the *Pomeranian*, the *Elkhound*, and the *Eskimo*, and like them, used in its native country as a utilitarian animal. In general appearance it is *Pomeranian*-like, and possesses the foxy type of head common to that group, has a short back, well-curved tail, thick coat that stands well out, and a nice frill. As is the case with this group generally, the *Samoyede* is hardy, very alert, and intelligent, while its temperament is of the best. White is the colour most in favour, and the dog measures about 20 in. to 25 in. at shoulder.

Fox Terrier.—These (for there are two varieties—smooth and wire-haired) are the most popular of all domestic dogs, and are too well known in regard to general conformation to need more than a brief description. Formerly they were the "Kennel Terriers" of the sportsman, but within the last half century they have become fashionable companions, pet, and show animals. There is nothing to choose between the two varieties, whose only points of differentiation are in the coat. The rough dog, however, requires a little more grooming to keep him in nice condition than the smooth. Contrary to the general belief, colour is of little importance so long as white predominates, and neither brindle, red, nor liver markings should obtain. Fox Terriers are handy, smart little dogs, as much at home in the water as on land, and among the best of all house guards. Both varieties require to be docked, rather more than half the tail being allowed to remain.

Great Dane.—Some may cavil at this breed being included as a pet dog, but as a matter of fact quite a number of ladies keep the noble Great Dane in this capacity and also as a companion and guard. It may be said to combine immense strength with great activity (we have seen one easily clear a five-barred gate) and a conformation that could scarcely be excelled. As a rule a pure-bred specimen that has been properly brought up is a dog most amenable to discipline and with a sweet temper. Conscious of his immense strength, unless unduly provoked, he seldom uses it, and for these reasons may be trusted in any company. Again, his sleek coat commands him as an indoor dog,

big though he be. Damp and draught are the great enemies to be avoided when keeping this lovely hound, which may be taught indoor manners as easily as can a toy animal. In appearance the Great Dane should be intermediate as it were between the Mastiff and the Greyhound, possessing neither the massive proportions of the one nor the slenderness of the other. The head and neck should always be carried high. Thirty inches is the minimum height of a dog and 28 inches that of a bitch; while the minimum weight of the former should be 200 lb. and that of the latter 200 lb. Brindle, fawn, blue, black and harlequin are the colours most admired. As in the case of the Borzoi, Deerhound, and Irish Wolfhound, the Great Dane must never be chained.

Griffon Bruxellois.—A Belgian toy dog that has gained many friends in this country. It is probably a compound of the *Affenpinscher*, *Irish Terrier*, *Yorkshire Terrier*, and *Rufy Spaniel*, but breeds true to type, and there are both roughs and smooths, the former being preferred. The Belgian dogs are cropped and docked, but the former is not allowed here. For a small dog this variety has a large head, rounded and covered with coarse hair, the lips being edged with black and carrying a moustache, the eyes large, black, or nearly so, and having long eye-lashes; the chin is prominent and has a beard. These dogs, which carry a red, harsh, wiry coat, weigh from 10 lb. or two up to 20 lb. They are engaging pets, very alert and active, but need to be kept indoors.

Irish Terrier.—Another deservedly popular member of the terrier group and one that on account of its hardness, gameness, and fine house-dog qualities has a very large circle of admirers. It makes a first-class town dog, its wheaten-red coat not showing signs of soiling. From 22 lb. to 24 lb. is the average weight of the best specimens. No special attention is needed to keep the dog in good condition. Occasionally an otherwise good dog shows a faint trace of white on chest. For a pet this of course does not detract from its value, though in the show dog it would. In outline the Irish Terrier is a graceful-looking not to say racy animal, and it should not be modelled on Fox Terrier lines.

Irish Wolfhound.—Though in reality a breed of modern manufacture that we owe largely to the work of the late Captain Graham, it is one which breeds very true to type. The constituents used in its making were no doubt Great Dane, Deerhound and Borzoi, with all that remained of the original Irish Wolfhound. The hound as we know it to-day is a monument to the skill of the breeder after over half a century of hard work. Endowed with great strength and activity, the Irish Wolfhound makes a splendid defender, while its amicable and quiet manner are proverbial. To the average person it does not attract the eye in the same manner as the Borzoi or even the Scottish Deerhound does, but for all that it is a variety that has quite as many good qualities as either, though it is not so athletic and a great measure of popularity. A typical dog should measure at least 31 inches at shoulder and go to scale at 200 lb.; and a typical bitch 28 inches and 90 lb. In general appearance this hound is heavier in build than the Deerhound, but not so heavy as the Great Dane—in fact it is strongly though symmetrically built. The colours are those met with in the Deerhound. The coat should be harsh on body, legs and head, and over the eyes and under the jaw very wiry and long.

Italian Greyhound.—One of the daintiest and most refined of all pet dogs. It may be described as a pocket edition of the Whippet, with a high-stepping free action, fine and supple skin, and a coat that shines like satin. The most desirable-sized specimens are those from 5 lb. to 7 lb. in weight, self-coloured fawn being the favourite colour. Brindled and pied hounds are not considered desirable. This little hound is too delicate to be allowed outside except in favourable weather, and it is usual to "sheet" it when giving it a run outside in winter and spring. To have this dog in nice trim it needs to be carefully fed and groomed. My lady's boudoir seems more suited to this aristocratic little hound than any other part of the house.

Japanese Spaniel.—An Eastern toy dog of

great beauty, the smallest specimens being called "sleeve dogs" from the fact that they are readily carried in the spacious sleeves of the Chinese. At one time it was regarded in this country as a rarity, but of recent years it has been bred in large numbers. Though still retaining a measure of popularity the breed has been to a certain extent depopulated from its high place by the introduction of its Pekinese relative. Fanclers set most store on the very small Japanese, and it is this craze which has largely proved the breed's undoing. Again, it is a variety which seems more than ordinarily susceptible to distemper. As pets the largest and the smallest animals are best suited, as they may be readily bred from; with the very small ones the risk is far too great to allow bitches to exercise their maternal instinct. Except that it is usually black and white and has a tail carried over the back, the Japanese in many features resembles the historic Blenheim Spaniel, though it differs from that dog in having the eyes set farther apart, in the face being broader, and in the skull being less rounded. Like the Italian Greyhound it has a distinctive high foot action. The weight may be anything from 2½ lb. to 1½ lb., and although black and white is the favourite colour, red and white is also possible. Whatever the colour it should be evenly distributed over the body, cheeks, and ears.

Maltese.—By some this is regarded as the oldest of all dogs. At one time it was classed as a terrier, but this of recent years has been altered simply to Maltese. Handsome in appearance, with a long coat that in whiteness rivals driven snow, and an engaging manner, it is little wonder that its admirers are many. Beautiful, however, as it undoubtedly is when kept in nice coat, it is far too delicate for most people, and is in reality a glass-case variety like the very long coated Yorkshire Terriers. The trouble of keeping these dogs in the peak of coat condition is too great for most people. Frequent washing, brushing, and occasional combing are necessary to the dog's well-being, and soap is considered injurious to the coat; beaten-up egg is far better for the purpose. These dogs weigh from 4 lb. to 9 lb., and the coat is parted down the centre from the eyes to the root of the tail.

Newfoundland.—No breed except perhaps the St. Bernard is so well known as the Newfoundland which Landseer has immortalised. It is, however, the white and black dog that the great animal painter selected for his famous picture, and this in respect of type is scarcely the equal of the more popular black. Originally introduced from Newfoundland the breed has been improved considerably by English fanciers and to-day it has a considerable number of followers. In its native home it was and is a worker; here it is merely used as a companion and guard. A characteristic of the breed is that it makes one, if not the, finest of all water-dogs, and it is a pity that this characteristic is not often developed. The Newfoundland is one of the breeds that in the past was given a bad name, being regarded as bad tempered. This, however, was an unjust aspersion and usually those specimens responsible for the circulation of an unfounded charge were mongrels. The general lines on which the dog is built are very well known; broad, massive head and flat skull, broad back, well-ribbed body and muscular hindquarters, and deep broad chest. In height 27 inches would be an average for a dog and 25 inches for a bitch; while in weight from 140 lb. to 250 lb. for dogs, and 120 lb. to 180 lb. for bitches, would represent about the means. Being a heavy dog, walking exercise only should be given. More than two years are taken by this dog to build up its huge framework, and a good deal of care has to be exercised if the forelegs are to be muscular, well-boned and quite straight.

Painley Terrier. (See *Glyndale Terrier*.)
Pekinese.—A very Eastern variety, which its name proclaims has its origin at Pekin, though not restricted thereto. With the Pomeranian it shares the honour of being the most popular toy dog known in this country. From 5 lb. to 10 lb. is the most desirable weight for one of these dogs, which are heavy in front and fall away on-like behind. Unlike the English Toy Spaniel, the Pekinese Spaniel has a flat skull,

and the tail is carried curled over the loins. The dog has a distinctly high action when walking; short, heavy, bowed fore-legs and lighter hind ones, hump-shaped drooping ears, and a very short and broad muzzle. The coat is long, with a thick under coat, and the thighs, legs, tail, and feet are profusely covered with feathering, while there is a full round the neck extending beyond the shoulder blades. Colour is unimportant. This is quite one of the most expensive of all dogs.

Pomeranian.—A foxy-haired, prick-eared, thick-coated dog, which of recent years has been dwarfed, the Toy specimens being those most in demand. Formerly the Pomeranian went to scale at 20 lb. or more; to-day 2½ lb. to 5 lb. specimens are those which fashion demands. Colours are very numerous—black, brown, fawn, blue, sable, red, orange, and parti-coloured, and prices for typical dogs rule high. The late Queen Victoria greatly helped to popularise these smart, active, toy dogs, whose chief drawbacks are that they are somewhat "yappy" and not as hardy as they might be. Their temperament, however, is of the best, and a marked improvement upon that of their progenitors, whose snapiness was proverbial. The Pomeranian of to-day is a compactly made, sleek dog with a well-knit frame and a profusion of straight coat that is prolonged into a frill at the neck and extends over the shoulders. This dog requires to be specially groomed: after brushing the coat in the ordinary way it should be finished the wrong way of the wool. Now and again a hair stimulant is desirable.

Poodle.—Second to none in intelligence Poodles both corded and curly have a very fair following. Generally speaking, however, the immense amount of labour and special knowledge required to keep them in nice order militates against their greater popularity. As pet dogs the Toy Poodles, weighing some 4 lb. or 5 lb. are those best suited. Though at one time it was considered that the corded and curly Poodles were two distinct varieties, it has been conclusively proved that they are one and the same, and that, according to the treatment it receives, the coat may be either corded or curly. The latter is the more popular dog. A typical Poodle presents a very symmetrical whole. The body is of a well-knit, compact straight and fine, with a slight peak to the skull. Black, white, red, and blue are the colours.

Pug.—Two distinct colour varieties of this pet-dog exist—the Black and the Fawn; the latter is a modern introduction (1886) that we owe largely to the late Lady Brassey. For a long time the Blacks ill-compared with the Fawns in quality, but now-a-days they are their equal in that respect. In build the Fawn pug is square and cobby, with a black face mask, large and deep wrinkles, a line (trace) extending from occiput to tail, a massive head without "stop," and weighs from 13 lb. to 27 lb. As house-dogs pugs do not excel.

St. Bernard.—As in the case of the Newfoundland there are two varieties, but these are differentiated not by colour but by the nature of the coat—Rough and Smooth. Contrary to the generally entertained opinion the lighter is the true mountain-dog though the former is the more admired. About the breed, generally, however, a halo of romance centres, and this adds to the interest. To Albert Smith, the traveller-lecturer, we are indebted for the introduction here of the breed which, though like most others has had its ups and downs, has always enjoyed a large measure of popularity. On several occasions £1,000 has been paid for a typical specimen, and even now the variety is not a cheap one to purchase. Nobility, strength, benevolence, intelligence and dignity are all to be seen in the St. Bernard, whose massive, broad, slightly rounded skull, short face, deep lips, small, dark eyes with the lower eyelid drooping, disclosing the "red" broad and straight back, well-boned ribs, and very muscular hindquarters are very well known. Standing at least 30 inches at shoulder and heavy in proportion, a St. Bernard is a most formidable dog when aroused, but generally speaking as quiet as the proverbial lamb. In the Rough variety the coat should be dense and flat and prolonged at the neck and ribs, and with well-feathered thighs; in the Smooth the

feathering on tail and thighs should be slighter and the coat generally bound-like. The markings of a typical dog add considerably to its beauty. They are—white muzzle, white blaze up face, white collar round neck, white chest, white fore-legs, feet and tail-tip, with black shadings on face and ears.

Belgian Sheepdog.—A forty-headed, prick-eared dog, from Belgium; tailless (but not naturally so); coat black. It is quite the smartest of all housedogs, though a trifle noisy by reason of its harsh "yap, yap." A distinctive feature is (or should be) the rounded guinea-pig rump. Its weight is about 12 lb.

Scottish Deerhound.—As is the case with the Borzoi this hound makes a very desirable companion and guard, while its temperament is of the best and its personal attachment remarkable. In reality the Scottish Deerhound is a Greyhound with a wiry coat, some three or four inches in length, but the body is larger than that of its smooth relative. Dogs measure at shoulder 29 inches to 33 inches and bitches 27 inches to 30 inches, while the former go to scale at from 8½ lb. to 105 lb, and the latter from 65 lb. to 60 lb. Dark blue-grey, dark and light grey and brindle are the colours most liked. Contrary, too, to what usually obtains, bitches of this variety are frequently of finer quality than dogs.

Scottish Terrier.—A powerfully built, sharp and active Terrier of from 15 lb. to 20 lb. weight, with a rather short, hard, dry jacket of steel-grey, iron-grey, black-brindle, grey-brindle, black, sandy, or wheaten colour, a fairly long, slightly domed head, carrying small prick ears, a flat-sided, moderately long body, and a tail disposed somewhat gaily. Though slightly headstrong and stand-offish in manner, this Terrier is nevertheless most affectionate and extremely intelligent, while as a housedog he is one of the best. Soundly conditioned he will thrive whether kept indoors for outside, and on the plainest of fare, but he is especially fond of plenty of exercise.

Shetland Sheepdog.—A comparatively new breed of pet-dog modelled on the lines of a Collie, but as yet showing no particular fixity of type. From 7 lb. to 10 lb. is about the weight, and the colours are those found in the Collie proper. It is, in fact, a Collie in miniature with a reputation for being one of the best of toy dogs in regard to amiability and alertness. In its native home it is employed as a worker.

Silkie Terrier.—(See *Clydesdale Terrier*.)

Skye Terrier.—A long and low Terrier carrying a double coat, the outer one long and covering body and face, and the under one short, soft and woolly. It is a charming dog for a pet, intelligent, and a first-class guard; while if kept purely for that purpose the abnormally long coat seen in the show animal is not required. The breed may be either prick- or drop-eared. The coat is either dark or light blue, or grey, or sometimes (though rarely) fawn with black points, but when born the puppies are black, or perhaps grizzly about the face. This dogs stands about 9 inches at shoulder, and weighs from 14 lb. to 18 lb. There is a short-coated offshoot of the dog known as the Cairn Terrier, which is likely to become fashionable at present it is in few lands. It is far more readily kept in condition than the Skye Terrier proper.

Toy Spaniels.—(English.)—These are four in number, Blenheim, Ruby, King Charles, and Tricolour. All have the same family characteristics—domed head, wide-apart eyes, well-marked "stop," *retrousse* nose with wide-open nostrils, and ears that nearly touch the ground. The only point of difference is the colour. In the King Charles it is glossy black and deep tan over the eyes and cheeks; in the Ruby, chestnut-red; in the Blenheim, white with chestnut-red markings evenly distributed and a white blaze extending from nose to forehead, in the centre of which is a red "spot"; in the Tricolour or Prince Charles Spaniel it is black, white and tan, the black and white well broken over the body and the tan distributed over the face, the lining of the ears, and tail. On account of the short face all the Toy Spaniels make a snuffling noise that is objectionable to many. They are not very good housedogs, and are somewhat delicately constituted. Against this must be set the fact that they are beautiful as to colouring and most affectionate in disposition.

Welsh Terrier.—A comparatively little-known member of the Terrier group, but one that makes a first-class pet and companion dog, while it is alert in the house, active outside, and very plucky. Though built somewhat on Wire-haired Fox Terrier lines the great width of skull between the ears, the deeper jaw, and the altogether stronger head, differentiates the Welsh Terrier from the more popular Fox Terrier named. In weight it is about 20 lb., and its shoulder height 15 inches in the case of dogs, bitches being correspondingly smaller and lighter. The coat—black-and-tan or black grizzle and tan—is hard, close and wiry, and does not show signs of soiling even in smoky towns, while the dog is hardy to a degree.

West Highland White Terrier.—In reality this is a working Terrier, but of late years it has been much popularised. It is the genuine working Skye Terrier, but white and short-coated and with a different muzzle from the Scottish Terrier proper. Still, since it has been popularised it is gradually becoming merged as regards type with the last-named dogs.

Yorkshire Terrier.—To keep this dog for show it really needs a glass case; but as a pet it may be allowed to run about the house. In that case the long coat, which is the glory of the show animal, must not be looked for, nor do we think it is desirable. The variety is one of the smallest of all dogs (we have seen 2 lb. dogs exhibited, and have owned them a trifle under this weight), but the minute 2 lb. to 5 lb. specimens are delicate; one 7 lb. in weight is far better. The body-coat is steely-blue, glossy and silk-like in texture, but that on the head and chest is a rich, bright tan. A peculiarity of the breed is that the puppies are born black and tan.

DOG MANAGEMENT.

Accommodation.—Dogs that are kept as pets may be allowed the run of the house, and even if they are placed in a kennel for a portion of the day, should always come indoors at night, where they are of three times the service they would be in a kennel. They should be provided with a definite sleeping place which they will quickly recognise, but which should never be on the ground level, where draughts are most prevalent. Baskets, boxes, and indoor kennels are to be had in variety, and these may readily be raised out of the way of draughts. Even a chair on which a special cushion is placed will make a snug and comfortable sleeping place. By way of "bedding" a rug, of material varying with the weather and the breed, will be quite sufficient for even the more delicate breeds. Still, if bedding as ordinarily understood be prepared, Elastene is hygienic, warm, and does not flatten like hay. In all long-coated breeds, however, a cushion, which must be kept clean and well beaten, is better than bedding. The covering should be of some cheap and washable material. So far as the harder terriers are concerned, these require little by way of bedding. The toy breeds when not kept in a special kennel should have a lined basket or box with a cushion for them to lie upon. Still, whatever sleeping place and material are used they should be exposed to sun and air in the daytime, and it is especially desirable periodically to treat them to an insecticide and to keep them free from dust, in which latter flea-larvæ thrive.

Appliances.—For the most part these will consist of brushes and combs, scissors, nail cutters, collars, chains, leads, and food and milk vessels. These latter must be kept scrupulously clean and wholesome, while brushes should be cleansed and disinfected periodically.

Breeding.—Where bitches are kept—and in many respects they are superior to dogs—they should always be allowed to breed. Once in two years is often enough. If they are prohibited from breeding they usually become very fat and are liable to lacteal tumours. It is not desirable to breed at the first "heat" which may occur at any time after about the seventh month, and spring is preferable to any other season. Twice a year bitches are available, there

being an interval of six months between the periods of oestrus or heat. The signs of this functional disturbance are a swelling of the parts accompanied by a reddish discharge. The time to mate the bitch is just as this ceases. The "heat" lasts from a fortnight to three weeks, and during that time the bitch must be watched, or she will leave the house and seek a mate for herself. The period of gestation is sixty-three days, more or less. For the greater part of the time no change in a bitch's daily life need be made—say for the first four or five weeks. After that care must be exercised that she is not over excited or allowed to exert herself too much, and especially to jump. A fortnight before her time she should have her whelping place appointed, and be allowed to go there each day until near her time. This will be heralded by a change in her behaviour, by a constant desire to go outside, and a general restlessness. Except with big-headed breeds like Bulldogs, healthy bitches require no help as a rule, though often small dogs when whelping like to have their mistresses by them. The event over, no attempt must be made to count or even to look after puppies. A little lukewarm arrowroot should be given her, and she should not be disturbed for going out until the next day, when she should be allowed out to relieve herself, and any soiled bedding should be removed. For three days soft food only should be given the nursing mother, after which a dietary on more generous lines than ordinarily given should be provided.

Docking, and Removal of Dew-Claws.—

These are two of the minor operations that even a pet dog breeder is called upon to perform unless he is prepared to seek the services of a veterinary surgeon. Quite a large number of the breeds enumerated are docked—Irish, Fox, Welsh, Alredale, and Yorkshire Terriers, English Toy Spaniels, Schipperkes, and Poodles. The operation is best performed during the first week of a puppy's life, it then inflicts a minimum of pain on the individuals on which it is practised. Having pushed back the skin and hair, the required length of tail may be removed with a pair of nippers or else with a sharp knife. In the case of the Schipperke only the veriest stump is allowed to remain, but in the other breeds, not quite half is taken off the terriers, and a little more than half off the Toy Spaniels, etc.

The removal of the dew-claws from the hind legs is a very necessary operation as such, if left, often cause the dog considerable pain should they get lacerated; their removal also gives him a more finished appearance about the leg. They may be removed about the same time as the tail is docked, using a pair of special scissors (obtainable from dealers in fanciers' appliances) and severing them in an upward direction.

Feeding.—An adult dog in health requires but two meals a day—a very light one of hard, dry biscuits in the morning, and a more substantial one late in the afternoon. If fed very late the dog will be asleep when most of its services are needed. The dietary should be varied—cooked lean meat, houndmeal, well boiled oatmeal or rice, any vegetables from the table but not too many potatoes, cooked fish freed from bones, and biscuits either broken up and given dry or covered with gravy, etc., and allowed to cool. The meals must be at regular intervals, and the dog given as much as he can comfortably eat. There must be no long fasts and no great feasts. After that the food vessel should be taken away, cleansed, and put aside until the next meal-time is due. The changes on the food should be rung as often as possible. Very occasionally, if a dog appears out of sorts, a little raw lean meat finely cut up will work wonders. Shy feeders and greedy ones need alike to be watched at feeding times. Large bones should always be provided after a meal, but not in place of one. Fish, game, poultry, and rabbit bones should never be fed to dogs.

Puppies require to be fed on the "little and often" principle. At the age of three weeks they may be taught to lap soft food from the mother's dish. Weaning (about seven weeks), however, is the most critical period in their lives, as the change from the mother's milk to that of the cow (far less nutritious) which is the general substitute, causes them to fall

away considerably. The best foods are Malt Milk or Lactol; while Benger's and Ridge's Foods with a little Plasmon are also excellent. Five or six meals a day are none too many for the weaned pup for the next two or three months. After the fifth month they may be reduced by two, as more sustaining food will gradually be given, until at the tenth only two meals will be necessary. Vegetables are not good for very young puppies, as they have a tendency to promote flatulency.

Exercise.—All dogs require exercise to keep them in health, the amount varying with breeds and even individuals thereof. With delicate toys this is often difficult to provide on account of weather conditions. In such cases then the little animals must be induced to run after a ball inside. Pugs and Bulldogs like slow walking exercise; the hardier terriers something more arduous, and two or three hours daily are not too many for a healthy adult. Exercise must never be given directly after a meal or in the heat of the day; nor must a dog be allowed to enter the water for a swim just after feeding. To allow any of the breeds enumerated to run after a cycle, trap, or motor, would be cruelly refined.

Grooming.—Regular grooming is as important as regular food; it keeps the skin and coat in nice condition and tends to prevent fleas and lice from affecting a lodgment. Brushing is better than combing for most breeds, and special brushes are sold for special breeds. Grooming should be performed before feeding. Sleek-coated breeds like Bulldogs, Black and Tan Terriers, etc., are best finished off with a chamomile leather and a good hand rubbing.

Training.—Pet dogs stand as much in need of training as the sporting dog used with the gun, though it is necessarily of a different kind. The first lesson must be obedience to name or whistle. The lessons must never be too prolonged or the puppy will weary. The fourth month will be early enough to commence. To collar and chain the animal must also be accustomed. Naturally he will resist both. If, however, they are put on when there is a prospect of a run out or a coup, and the chain be allowed to drag, the puppy will soon forget that they are restrictive agents. Indoor manners must be early inculcated. Every time the puppy offends he should have the soiled place pointed out and be put outside in disgrace. On no account thrash him or the fault will be intensified—not cured. Having expiated his offence let him again return indoors and do not scold him unless he again offends, when the process of ejection may be repeated. Outdoor manners will consist of thorough obedience to call or whistle, to come to heel when told, and to respect domestic and other stock. This last may be brought about by taking the puppy where cattle, horses, sheep, and poultry are. At first he will be on a lead or chain, but later this may be dispensed with. Any attempt to break away must be checked by warning voice, but severer measures must not be resorted to until every other means have failed. With some dogs it is quite sufficient to put them on the lead at the first sign of breaking away and allowing them to cover the remainder of the journey restricted and in disgrace. Puppies should never be fed from the table or allowed to take anything from strangers, otherwise they grow up intolerable nuisances. Again they must never be allowed to jump up, say, when an owner meets a friend, or to bark at horses, cattle, or other stock. Any attempt to do so must be nipped in the bud, or a well-mannered adult will never result.

COMMON DISEASES AND PARASITES.

The diseases and parasites affecting dogs are exceedingly numerous—so numerous that to deal with all would require a volume. All that can be dealt with, and these very briefly, are such as are commonly met with, and that will yield usually to home treatment.

Anæmia.—Dogs that are badly fed and housed, or which suffer from worms, are often anæmic, and in that condition Blotch or Surfeit—characterised by the appearance of reddish patches and finally by sores—

results. With anæmia the gums and mucous membranes are pale and bloodless, and the animal sometimes falls away considerably. Good nourishing food and a healthy environment are very beneficial. Occasionally a little fresh, raw meat, finely chopped, will do a lot of good. An excellent drug is reduced iron (tasteless), 1 gr. to 3 gr. in the food twice a day.

Scotch or Surfeit.—Really a phase of Eczema in which there are inflamed patches and large sores. It may be due to poorness of blood (Anæmia) or to an overcharged system. A remedy in the former case has been suggested under **Anæmia**; while in the latter a brisk purge is called for until the bowels are moving freely. To the sores themselves boracic acid ointment should be applied.

Canker of the Ear.—An exceedingly common disease of the dog that manifests itself in two forms—internal and external. The internal form may be due to a Symbiotic parasite that sets up great irritation, or to some injury or foreign substance in the inside ear with suppuration and an objectionable smell. The external form affects the ear-flap. The symptoms are a shaking of the head and a pawing at the ear, with, of course, a redness inside the ear or inflammation, and perhaps ulcers outside. For the external canker it is just necessary to cleanse the ear by means of Condy's Fluid (a light red solution), and afterwards to apply, when thoroughly dry, oil of sweet almond of Peru. In internal canker the ear should be gently syringed with spirits of wine and lukewarm water (one in twenty). After that well dry with successive pieces of cotton-wool rolled round the pointed end of a penholder, and finally blow through a quill or glass tube equal parts of finely-powdered iodoform and subnitrate of bismuth. Feed lightly and keep the bowels well moved.

Cough.—A symptom and not a disease proper; often due to derangement of the organs of respiration, but occasionally to worms and indigestion. Where in addition to the cough there is a rapid rise of temperature, quick, laboured breathing and expectoration, bronchitis may be suspected, and skilled aid should be sought. In the other two cases the cause must be removed, when the cough will cease.

Deafness.—With white dogs especially this is a fairly common disease. Usually with them it is congenital and incurable. The condition may, however, arise from a secretion of wax, and in that case gentle syringing with lukewarm water, careful drying of the ear, and the insertion therein of a little almond oil, warmed in a spoon held over a spirit flame, will give relief.

Diarrhoea.—An extremely common ailment with dogs and puppies, and one that must never go unchecked; on the other hand, it must not be stopped directly a looseness of the bowels is noted, as that is Nature's way of getting rid of some undesirable matter. A good plan is to give a dessertspoonful or a teaspoonful of castor oil. Worms and unsuitable food are commonly responsible for the trouble, while an injudicious use of flowers of sulphur may now and then be the cause. Still, whatever the cause, the oil suggested will do good, and this may be followed by 5 gr. to 10 gr. of subnitrate of bismuth dry on the back of the tongue. The food, too, must consist chiefly of arrowroot and milk or of peptonised milk. Well-boiled rice, with which some shredded raw lean beef or mutton has been mixed, may also be given; but the rice must be *thoroughly cooked*, or further trouble may result. Young puppies with the dam should not have drugs; they should be treated through the mother, but older ones may have half a teaspoonful of ordinary chalk mixture.

Distemper.—The commonest and most fatal of all dog diseases. Though usually a disease of puppyhood it also attacks adult dogs. One attack of the disease does not render an animal immune, but second and third attacks are as a rule lighter. All dogs do not have distemper, though the number which escape is relatively small. It is a many-phased disease that runs a specific course, and though certain drugs are helpful, the patient depends for recovery still more upon good nursing. The great thing is to treat the disease directly it is recognised. The usual form is characterised by running of the eyes and nostrils, a hot nose, and a decided rise in temperature. The

first thing to be done is to remove the dog to warm, airy quarters, where he will receive constant attention. It is very essential that the discharge from the eyes and nose be kept removed. Once the nose gets clogged with the mucus, complications are sure to arise (the lungs and the bronchi may become involved), and the case is not then amenable to home treatment. If ordinary invalid food is refused—as it frequently will be—the following must be given three or four times daily:—Bovril one teaspoonful, milk 2 oz., and half an egg. In addition a fresh egg should be beaten up in a little milk; this is sustaining and will also help to moisten the patient's mouth. These preparations must be given quite fresh. Still better fare if the dog will take it consists of a sheep's head boiled and the meat therefrom cut up finely and mixed with stale bread—the whole covered with the liquor in which the head was boiled. St. Vitus Dance (Chorea) often follows a distemper attack, and is incurable. Those whose business it is to wait on distemper patients should not be allowed access to healthy dogs, cats, or even ferrets. After the patient becomes convalescent he will be so debilitated that a generous, readily-digested dietary must be provided for a time.

Eczema.—Another disease with many phases and difficult in bad cases for a layman to differentiate from Sarcopic Mange. There are both wet and dry forms of eczema, and both are characterised by considerable skin irritation. The cause of disease in any individual may be very obscure. It may be due to a lack of food or from a surfeit thereof, or even from an unsuitable dietary, or from worm infestation. Contrary to the opinion often entertained, Eczema is not due to a parasite (as Mange in both forms is), but is really a blood disorder and therefore non-contagious. The skin often presents a very red appearance, especially in the thigh region, when the disease is known as Red Itch; or in addition to the inflamed condition there may be bladder-like eruptions which, when discharging their contents, form scabs and coalesce. To attempt to allay the irritation (the effect) without attacking the cause is not of any permanent use. The cause must be diagnosed and efforts made to remove it and to bring about a healthier condition of the blood. For this, from a dessertspoonful to a tablespoonful of the following should be tried:—Liquor arsenicalis, 1 dr., tincture of ginger 4 dr., Epsom salts 2 oz., water 6 oz. To allay the skin irritation use one part of flowers of sulphur to six parts of olive oil. Scottish and several other Terriers seem particularly susceptible to a form of wet eczema between the toes. For this boracic acid is excellent.

Fits.—Those most commonly met with are due either to teething or to epilepsy. The former are not of great moment, and usually an aperient at the time the permanent teeth are erupted will prevent them. Epileptic fits are more serious. The dog when seized seems to tremble violently, staggers, and falls down, but he attempts to move. They are usually accompanied by a frothing at the mouth, clamping of the jaws, violent convulsions, and a moaning cry. Beyond removing the animal to a quiet spot little can be done. When the fit is over the animal will collect himself, and will get up apparently all right. Bromide of Potassium in 2 gr. doses, twice a day, will have a quieting effect on the nervous system; but care must be taken not unduly to excite a dog showing a predisposition to these fits, or to give exercise on a full meal. Worms, too, are a cause of fits in both puppies and adults. The remedy is to expel the parasites.

Fleas.—Dogs that are neglected (ungroomed) on whose sleeping-places are not looked after, are very liable to flea attacks. These are found on the dog as perfect insects only, the larval (grub) and chrysalis stage being passed in dust and other debris. There are plenty of soaps on the market that will kill fleas; while Jeyes' Fluid in solution will also be equally useful. In the smaller dogs (toys) a spraying with camphor spirit, followed by a combing, should get rid of the vermin; but care must be taken that the spirit does not get into the eyes. Baskets, cushions, and rugs should be periodically cleansed and treated to an insecticide.

Indigestion.—Another common ailment generally,

the result of improper feeding and lack of exercise and fresh air. The chief symptoms are an unhealthy appetite (craving for cinders and coal), diarrhoea, bad breath, vomiting and constipation. A compound rhubarb pill—or two in the case of the larger dogs—given on alternate nights for a week, will soon work an improvement if at the same time attention be given to dietary and exercise.

Lice.—Two kinds of lice are found on the dog—a biting and a sucking kind. They are usually more difficult to get rid of than fleas by reason of the fact that not only have the insects themselves to be taken into account, but also the unhatched generations in the egg-cases ("nits") attached to the hair-shafts. All hair-combings should be burned directly after grooming, and the dog dressed with one part paraffin and two parts olive oil. The egg-cases may also be dissolved by means of vinegar. "Jeyes' Fluid (one in fifty)" is also a good insecticide. Lice are debilitating to their host, and are, moreover, the intermediaries of Tapeworm and thus doubly objectionable.

Mange.—Though often spoken of in connection with dogs, Mange cannot be regarded as a common disease in either the Sarcopic or the Follicular form. As it is communicable to man—at least in the Sarcopic form—home treatment is not advisable. Again, at the outset it is difficult to differentiate it from Eczema. Later, however, the shedding of the coat and the unwholesome appearance due to the bursting of the pustules, the exudation of a fluid, and the coalescing of the scabs, should be sufficient to warn the owner. Mange is due entirely to parasites, the one burrowing under the cuticle, and the other beneath the hair follicles. It is highly contagious, and a kennel or other sleeping-place used by a mangy patient should not be occupied by a healthy dog until it has been thoroughly disinfected, and then only on the advice of a veterinary surgeon.

Rickets.—Puppies bred from rickety parents, or reared under unhealthy conditions, or fed on an unsuitable diet, are liable to contract this deforming disease. It is caused by a deficiency of earthy matter in the limbs chiefly, and the result is that they are unable to support the body-weight and become misshapen. Moreover, once the limbs are crooked the deformity is permanent. The great thing to aim at is prevention. This is best brought about by finding a good substitute for the dam's milk at weaning time

(see *Feeding*). Ten grains of phosphate of calcium given in the food twice a day should also prove of great benefit.

Ringworm.—Two varieties of Ringworm are found on the dog—honeycomb and circular. The fungus responsible therefor is easily introduced into an otherwise healthy area by means of cats, cattle, etc. Affected animals should be isolated directly the disease is noticed, and dressed with yellow mercuric oxide ointment. Ringworm is very contagious and transmissible to man.

Ticks.—Pet-dogs that have the run of the country are almost certain to pick up Ticks—animals which approach the spiders in form. They are very irritating as well as debilitating to their host. When first they attach themselves they are quite small, but gradually assume goodly proportions, and when full fed are not unlike a plump horse bean. They should never be picked off, as in doing so the mouth-parts of the creature are invariably left, and these cause nasty sores. If not very numerous they should just be touched with a camel-hair pencil dipped in turpentine. This will cause them to relax their hold, and they may then be readily detached and crushed. Washing with soap is of no avail against Ticks. Several firms of repute sell efficacious lotions to be used against the pests.

Worms.—Round, Tape, and Thread-worms affect the dog and are the cause of much trouble. Puppies nearly always harbour the kind first mentioned, and they are detrimental to their health. Pot-bellied individuals should always be suspected, and a vermifuge be given. Sherley's Worm Capsules are safe and effectual. For Tapeworms (usually passed in flat segments with the *feces*) oil of male fern in capsule form and in doses suited to the different breeds is almost a specific. All vermifuges should be given after fasting the dog twelve hours, and should be followed in half-an-hour with a dose of castor-oil—a dessertspoonful to a tablespoonful. So long as the head of the creature remains, however, the worm will continue to increase by budding off segments from the head. By way of prevention all dogs should be kept free from fleas and lice, and on no account should they have access to uncured rabbits' livers or sheep's heads, either of which may be the means of infesting the dog with Tapeworms of a most injurious kind.

Thread-worms may be ousted by similar means.

CATS.

The cat may be truthfully classed as amongst the most beautiful, elegant, and graceful of all carnivorous mammals, while its agility is nothing short of remarkable. It is, moreover, an animal of great utility, and assists materially in holding in check two of the most destructive of all vermin—the rat and the mouse. In the days of Julius Caesar, although our forests were plentifully supplied with cats, not a single "mouse" existed in any British town or village. And further, it is recorded that the domestic cat was a rarity even a thousand years after. Cats have been kept as pets though for hundreds of years now, and once having proved their value to man as destroyers of vermin became greatly valued.

VARIETIES.

In a general way Domestic Cats are divided into two classes—Long-haired, and Short-haired. As exhibition specimens the Long-haired are much the more popular, but the latter are much the more numerous, and largely kept as household pets.

Long-Haired Cats.—Not many years ago these were judged for coat and size only, and the colours were few; now there are many—Black, Blue, White, Orange, and Cream in Self; Brown, Silver, Orange, and Blue in Tabbies; Tortoiseshell, Tortoiseshell-and-White, and Blue-and-Cream in Broken Colours. The most valuable and highly-prized colour of all is, that known as Chinchilla. The Chinchilla is a cat that is practically a silver, but its fur is just flecked or tipped very faintly with grey. The Smoke possesses an under coat of pure silver, whilst its top coat is a rich black. A sound-coloured Smoke must not show any barring or tabby marking. Its under colour must be as clear and pure as its top coat is bright and sparkling. Although springing from one common ancestry, the Smoke and the Chinchilla have nothing in common

except the colour of under coat. The top coat of the one must be as light as possible, and that of the other as black as possible. The Chinchilla has a green eye, peculiarly beautiful and lovely, but the eye of the Smoke has been improved into a rich amber of a coppery hue.

The most popular of colours is that known as blue, but strictly speaking the colour is more of a French grey than a blue, although there is one family of Blues which possesses a warm and deeper tone, and is more of a plum blue. This particular strain has been in great request of recent years, and one of its members, known as Champion Sir Archie II. of Arrandale, has produced more winning cats and kittens than any cat ever bred. The eye of the Blue must be deep amber or copper coloured if it is to be accounted of value on the show bench. Blacks, Brown Tabbies, Orange Selfs and Tabbies, Smokes, Creams, Tortoiseshells, Tortoiseshell-and-Whites, Blue-and-Creams, and Blue Tabbies should all have orange or amber coloured eyes. Silver Tabbies should possess a dark hazel eye. All the best authorities are agreed on this point, although of late years one or two prominent judges have stated their preference for the green eye, but

their opinion has not been shared by the leading breeders. Whites have blue eyes.

As the Tabbies are named after the ground colour of their coats—Brown, Silver, Blue, and Orange. The stripes of the first three must be black, whilst those of the Orange are of a richer and deeper hue than the ground colour, and a good description to apply to them would be red. In fact some people speak of Orange Tabbies as Red Tabbies, but that is hardly accurate. Orange and Cream Selves have one common ancestry, and have come from the crossing of Blue Selves and Orange Tabbies; then inter-breeding the progeny, and making careful selection from each succeeding generation, until now the two colours are established and breed fairly true. An occasional cross between the Orange and the Cream is beneficial to both, but particularly so to the Cream, because it keeps up the colour without any further admixture of blue. Blacks must be as deep rich and bright in colour as possible. It is somewhat remarkable that the best coloured black cats are usually very rusty and brownish in their top coat as kittens. Therefore a kitten should not be rejected on account of its colour until it has shed its kitten fur, and rejoices in the possession of its full adult coat. Tortoiseshells are tri-coloured, having distinct patches of black, red, and yellow, and the richer, deeper, and clearer these three colours are so much more valuable the animal. Thus far the Tortoiseshell Tom is the *seignior* of the Cat Fancy, only two or three specimens having made their appearance. Tortoiseshells are bred from the crossing of Blacks and Oranges, and from either of these colours with Tortoiseshell. At one time Orange females were as rare as Tortoiseshell males, but now they are fairly common. The writer was, we believe, the first breeder to produce Orange females. Whites are very handsome and are highly esteemed on the show bench.

The chief points of the Long-Haired Cat apart from colour, which is a very weighty consideration, and a point of great value, are—Head, round and compact as possible, bold in the forehead, short in face, full and round in the cheeks and lower jaw; the nose should be short and wide, and have a slight upward tilt; the eyes should be round, full, bold, and bright; a lustreless eye is a great drawback, and ears should be short, neat, well tufted, and widely set in the forehead. Body, compact, cobby, and firm. Legs, stout, strong in bone, well covered with fur. Feet, broad, well padded and nicely tufted. Ears, collar, long, full, and flowing. Tail, short, wide and bushy, and carrying a profusion of fur, hence the cognomen "brush" so often applied.

Short-Haired Cats.—In coat and structure the Short-Haired Cats differ very materially, not only from the Long-Haired but also from each other. All the Long-Hairs are alike in shape, coat, and carriage. Not so the Short-Hairs. There is only one variety of Long-Haired, but there are five varieties of Short-Haired—British, Manx, Abyssinian, Russian, and Siamese. Another variety is sometimes spoken of as the Maltese, but it is not recognised by English breeders.

We will speak of the British first. The ordinary household cat or family mouser. It is more elongated in body, legs and tail than the Long-Haired Cat. The head, although full and round, is not so short in face and nose as that of the Long-Haired. It is free in its movements, and possesses a more vigorous and swinging gait than does the Long-Haired. The colours are—Black, Blue, White, Orange, and Cream in Selves. Brown, Silver, Grey, and Orange in Tabbies. In eye colour they are the same as the various Long-Hairs, as are the two other colours, Tortoiseshell and Tortoiseshell-White. The coat of all British cats is soft, fine, sleek, and velvety.

Manx Cats are tailless. They are not so elongated in body as the British, the hindquarters having a sort of chopped-off appearance; they are not square, but rounded; the hind legs are unusually long, thus the body slopes towards the shoulders, instead of from them as in the British cats. The Manx cats are devoid of the graceful carriage of the British, and have a kind of louncing gait, something like that of a rabbit.

Abyssinian Cats.—These bear a close resemblance to the Egyptian cats, and many believe them to be direct descendants of the original Egyptians. The name Abyssinian suggests a connection with Egypt,

and the fact that they are quite distinct in colour from any other cats known to English breeders also lends colour to the Egyptian theory. The body is long and slim, as are the legs and tail. The face is more wedge-shaped than that of the British. The ears are rather long and fine and tipped with black. In colour it is brown, and is evenly ticked with black. Silvers have been produced, but the best authorities say they are not pure, and are the result of being crossed with the British Tabbies. This contention may be correct, but we are inclined to dispute it. In our opinion the Silvers are sports from the Browns, and are the result of a failure or weakness of the colouring pigment.

Russian Cats.—These are beautiful rich lavender-blue in colour, a brighter and more metallic hue than the blue of the British Cat, which they resemble in body shape but not in head, the head being longer and not so massive as that of the British. The coat of the Russian is altogether different to that of the British, it is not so soft and velvety, but is closer and firmer, and possesses a plush-like appearance and feeling. The eyes are not so deep in colour as those of the British Blue, and often show a shade of green. English breeders like the deep coloured eye, but the paler shade is more in keeping with the colour and texture of the coat of the Russian.

Siamese Cats.—As the name indicates these are the Royal Cats of Siam, and they are most distinctive in shape of body than any of the other breeds. The British Cats are more delicately formed, are finer in bone, and somewhat shorter in limb. The head is fine, but not so long nor so wedge-shaped as that of the Abyssinian. When young the Royal Cat of Siam is of a clear cream colour, but as it ages the colour darkens to fawn, and from fawn to chocolate. It has clear china blue eyes, and its face, ears, paws and tail have rich seal-brown markings. They are hardly if kept under proper conditions. There is a blue variety, but only a few have been imported into England.

MANAGEMENT.

Breeding.—No better place for the early home of kittens can be desired than a cheese tub. One of these will only cost a few pence from the local grocer, and when scrubbed and cleaned needs nothing more than a piece of old blanket or flannel laid in the bottom to make a very comfortable bed for a breeding queen. Pussy should be introduced to her quarters about a week before the kittens are expected, and she will soon understand and appreciate them. The blanket or flannel should be changed every few days, then no trouble will be experienced from fleas, especially if the bottom of the tub is wiped out with a cloth and dusted with pyrethrum insect powder each time the blanket is changed. The welfare of a litter of kittens depends in great measure upon the cleanliness of their bed, as it is impossible for them to thrive if a colony of fleas are sucking their life blood from them. It is not advisable to mate a queen before she is twelve months of age, nor to allow her to have more than two litters in a season if it is desired to have strong, robust, healthy kittens. When a queen shows signs of becoming restless, she should be shut up until arrangements can be made to send her away to be mated, so that she may not contract a misalliance. Nine weeks from the time of mating kittens may be expected.

Feeding.—For the first seven or eight weeks the kittens will do well enough with their mother's milk. Then they may be given a little cow's milk, thin gruel made with oatmeal and milk, and a Benger's or Ridge's Food. At nine weeks they should be given porridge made from milk and rolled oats such as Quaker, Provost, or Waverley. At twelve weeks they may have a little minced beef cooked with their porridge; as change of food they should be given pithy, or dog, biscuits broken up and cooked as porridge. This diet may be continued until the kittens are seven or eight months old. Many give kittens raw minced or scraped beef from the age of three months, but it is not needful; in fact, our experience leads us to the conclusion that young kittens do better without, than with, raw meat. Young kittens when weaned need to be fed five or six times a day, say, every two

hours; when three months, every three hours; from six to eight months, four times a day; after that age, twice a day. For adult cats the diet should be varied, and may consist of fish, meat (cooked or raw), gravy, vegetables, boiled tripe, table scraps, bread-crumbs, and any of the ordinary household meals, and dog biscuits which may be scalded and mixed with meat and vegetables or fish, or fed alone. Milk we do not care for as a food for cats after early kittenhood; we long ago came to the conclusion that they do far better without it. There is one thing, however, which should never be forgotten, and that is a dish of clean cold water renewed twice a day. With this, and care and cleanliness, there will not be much illness. Kittens will learn the use of the sanitary pan from their mother, and will use it regularly from the earliest days of kittenhood if permitted. Finely sifted ashes are the best material for the pan, but powdered peat moss or dry earth are efficient substitutes.

Grooming.—The health and general well-being of depend greatly upon the way in which their bodies as well as their beds and resting places are cleansed. Every day the coats of long-haired cats should be well brushed with a long-bristled brush such as ladies use for brushing their tresses. Combs should never be used unless absolutely necessary, as they tear the coat and destroy its beauty. If the coat should become matted and cutted, the cats should be teased out with a long drawing needle, then gently combed, and afterwards brushed out. If neglected, the coats will soon become matted; therefore, the daily use of the brush should not be neglected. Before showing, the coats of Blues, Blacks, Browns, Creams and Oranges should be dry-cleaned with warm bran, which should be well rubbed into the coat with the hands and then carefully brushed out. Whites, Silvers and Chinchillas should be cleansed with baked flour or with Pears' Prepared White Fuller's Earth, rubbed in the same all brushed out. It must be remembered that the daily grooming does more than add to the cat's outward appearance; it keeps it in good health by preventing the loose fur from entering the cat's stomach and causing fur balling. In connection with this, we may say that cats who are able to eat long coarse grass are seldom affected in this manner, the grass preventing the balling by reason of its power as a natural emetic.

DISEASES AND PARASITES.

Canker of the Ear.—A disease that might be treated on the general lines suggested for dogs.

Cold in the Head.—Sneezing, coughing, and eye and nose discharge are the symptoms. The treatment consists in keeping the cat warm and giving light, easily-digested food. Should the discharge close the nostrils, the cat's head should be held over a vessel of hot water containing a little Eucalypti Oil or else a decoction of Poppy Heads. This complaint is very contagious.

Diarhoea.—Symptoms too well known to need description. (Observe the same general rules as are detailed for dogs.)

Distemper.—A highly contagious disease characterised by loss of appetite and weight, and a hot nose; it is usually followed by diarrhoea, or it may be by vomiting, discharge from the eyes and nose, coughing, and sneezing. Another phase of the disease shows the cat as a most emaciated animal, with a dry, staring coat and cold skin; death usually soon puts an end to its sufferings. Pneumonia, again, often follows on distemper, and is very fatal. The best thing to be done is to send for a Veterinary Surgeon.

Eczema.—A non-contagious skin trouble in which there is great irritation, causing the cat to scratch itself and scabs to form, especially on the back. In certain cases where there is no inflammation present, arsenic is the best drug to employ, but in infinitesimal doses, and only under the advice of a Veterinary Surgeon. A little lean, raw meat cut up in good, and the bowels should be kept gently moved. To relieve the inflamed skin apply three times a day: Goulard's Extract, 1 part; Glycerine, 4 parts; Rectified Spirit, 4 parts; Water, 75 parts.

Fits.—Epileptic fits are common. Adopt general

treatment advised for dogs. Three-grain Bromide of Potassium tablets should be dissolved in a little water and given as a sedative.

Fleas.—These are especially troublesome in the case of long-haired cats. They are best got rid of by spraying with spirit of camphor from tail to neck (taking care that none gets in the eyes), and then combing the cat over a vessel of hot water.

Fur-balling.—This is not a disease although it often gives rise to one, and is not infrequently the cause of a cat's death. Usually the cat owner resorts to castor-oil, and thus makes matters worse. The best thing to be done is to get a pigeon and to give a wing—feathers and all—to the cat. This will usually dislodge the fur "ball" without much trouble.

Gastro-Enteritis.—Perhaps the most fatal of all cat diseases, and usually due to erroneous feeding, or the cat eating garbage. The "stools" are greenish and most offensive; there is much fever accompanied by a swelling and tenderness of the stomach. It is infectious and the aid of a Veterinary Surgeon should at once be enlisted.

Lice.—A biting louse is found on the cat. It does not seem to cause much irritation. It may be destroyed by using creolin 1 part, water 200 parts twice a week. Fatty food is called for, and cod-liver oil will be found of benefit in such cases.

Mange.—A somewhat intractable disease not amenable generally to home treatment.

Milk Tumours.—These unsightly swellings are due to unthanking people destroying the whole of a litter of kittens and not attempting to disperse the milk. When all the kittens are taken away from the mother while she has plenty of milk, the latter should first be drawn off and the milk-glands rubbed with camphorated oil.

Ringworm.—An irritating skin condition due to a fungus, and as the complaint is communicable to man, it is best treated by a Veterinary Surgeon.

Worms.—Both Round and Tape-worms are found in the cat. For the first give to an adult: area nut, 6 grams, santonin, 1 gram, followed in an hour by 1 dessert-spoonful of castor-oil. For the Tape-worms Oil of Male Fern (obtainable in capsules) is excellent. After the expulsion of the parasites the cat will need to be generously fed.

GOATS.

Disposition and Tractability.—Goats are capable of being made as companionable as dogs. They should be taken in hand when quite young, a well-bred kid being far easier to procure than a full-grown goat, which may cost anything between £5 and £10, whereas a kid may be had for a pound or thirty shillings.

Rearing Kids.—Our advice to beginners is to write to some of the principal breeders of the British Goat Society, and endeavour to purchase a female kid from parents possessing a milking pedigree, which means one whose dam or grand dam has won a milking prize, showing that the progeny are likely to inherit this quality.

Many goats produce three kids at a birth, but it is better to rear two well than three indifferently, and therefore breeders may often be willing to part with the third at a reasonable price, and this is the chance for the novice. The sooner the kid is taken from its mother after birth the easier it is to rear by hand, and artificial feeding is easily managed if the following conditions are observed:—The first and most important is to pay the greatest attention to cleanliness in the utensils used. The feeding-bottle should be one of those having a teat fixed to one end and not one connected by a long tube which accumulates sour milk and is difficult to clean. It must be rinsed out with scalding water once a day at least, and occasionally left soaking in soda water. The best milk of course is goat's milk, but as this is not often obtainable where a goat is not kept on the premises, the cow's milk may be substituted, a quarter of a pint at a time, repeated several times a day for the first week. Afterwards the meal may approximate to half a pint and be repeated less often. At a week old a quart a day may be given

and this may be gradually increased afterwards. At the end of a month, if economy has to be considered, soft calf-meal gruel may be given mixed with the cow's milk, and continued in larger proportion as the animal grows, till at two months old this artificial food may be supplied alone or at least with only a small proportion of milk. At ten weeks the kid may, if desired, be gradually weaned from the bottle and encouraged to eat hay—which it will have already nibbled freely if offered—and crushed oats mixed with bran. It will be found beneficial, however, to continue the liquid nourishment night and morning for another month or longer.

Goatlings.—Technically speaking a kid is a young goat up to twelve months old; from that age to two years it is known as a goatling, which corresponds to a heifer amongst cows. Now a goat is the most precocious of probably all domestic animals, and if allowed the opportunity it will mate even before it is fully weaned, and bring forth a kid before it is itself out of its kidhood. This must be carefully guarded against by anyone wishing to rear a fine goat, for this early breeding arrests growth, and the animal never attains afterwards its proper development. Sex kids and goatlings must therefore be kept quite away from male kids or goats.

Assuming the kid to have been born in March, it should not be mated until the September of the year following. As the period of gestation is five months it will then come into profit the following February or March, when it has practically done growing.

Training a Goat for Domestication.—It will be during the goatling stage, and in fact, as soon as it is no longer a kid, that the animal should be trained for drawing a carriage if such be desired. The first thing to be done is to accustom the animal to a bridle and bit, and then to drive it about with a pair of reins but without being attached to any vehicle. This is to teach it the use of the bit and to get it to answer to the rein, turning to right or left and stopping as required. The goat is then attached to a light cart, being at first led by hand, and afterwards driven until it understands what is expected of it.

Feeding.—Grass is by no means a necessity. The animal enjoys pasture naturally, but the grass must be clean and sweet; trimmings of hedges and prunings of trees form admirable food. There is, indeed, nothing in a vegetable garden, from such weeds as thistles and docks to peashum and potato tops, stalks of greens, etc., that comes amiss to these animals.

When the time of the year arrives in which garden produce is no longer available, recourse must be had to hay and oats, with swedes or mangolds as green food, and such scraps as the kitchen affords in the way of pieces of bread, apple and potato parings, the scrapings of the porridge-pot, and such like. It is out of waste material of this kind that the pet goat provides the household with the most nourishing and digestible of milks—a milk which gives a creamy taste to your tea and coffee, and the puddings that are made with it.

RABBITS.

England has long bred the lead so far as the breeding of high-class exhibition rabbits is concerned, but on the utility side is a long way behind the Continent so far as the production of rabbit-meat and valuable skins are concerned. This reproach is likely to be swept away in the near future, as quite recently two associations have been started to promote the cultivation of rabbit-breeding solely for the sake of the skins and meat. When we consider that all domesticated rabbits are descended from the brown, or grey, rabbit (*Lepus cuniculus*), so familiar to us all, we are led to realise how great has been the ingenuity and perseverance of fanciers in the production and perfecting of the many varieties which now grace the benches of our shows. This work has been greatly assisted by the many specialist clubs devoted to the culture of Fancy Rabbits. If, by the influence of the new utilitarian societies we are led to consider the commercial value of rabbit-breeding, England will quickly beat the Continent in the production of valuable, beautiful skins, if not as far as table-meat is concerned.

Varieties.—(1) Angora: points—long fleecy coats,

heavily tufted ears and feet; colours—white, black, blue, fawn and grey, the first the most common. (2) Belgian Hare (bred to the type of the wild hare): points—length of body, fine head, fineness of bone, and rich silvery red colour. (3) Dutch: points—smart cobby body, close fine coat; markings—white blaze collar and feet stops; colours—black, blue, light and dark grey, tortoiseshell, yellow; weight 5 lb. to 5½ lb. (4) English: shape, size, full close coat; markings—butterfly, nose, eyes, ears, cheeks, saddles, body, legs and belly; colours—black, blue, grey, tortoiseshell. (5) Flemish Giant: points—size, massive bone, squareness of body, firmness of flesh; colour—steel-grey; weight 15 lb. to 20 lb. (6) Havana: points—fineness of bone, racy appearance, fineness of coat; colour—chocolate-brown, like a choice Havana cigar. (7) Himalayan: points—small cobby body, pink eyes, close fine coat; colours—white, with black nose, ears, feet and tail. (8) Imperial: points—medium size, short fine silky coat, blue eyes; colour—medium blue; weight 5 lb. to 6 lb. (9) Lop: points—length, width, substance, and carriage of ears, size of body, straightness of limbs; colours—black, black and white, blue, blue and white, fawn, fawn and white, grey, grey and white, sooty fawn, and tortoiseshell; the ears of first-class specimens measure 27 to 28 inches from tip to tip, and 7 to 8 inches across. (10) Polish: points—neat cobby body, short ears, pink eyes, short fine coat; colour—white. (11) Silvers: points—short cobby bodies, but larger than Polish or Himalayan, evenness and silveriness of colour, brightness and sharpness of silvery ticking, short fine coats, fine bone, neat ears; colours—grey, fawn, brown, blue, divided into shades known as light, medium, and dark in each of the four colours; weight 5½ lb. to 6 lb. (12) Tans: points—shape of body, fineness of bone, sharp, alert expression like unto the wild rabbit; colours—black, and blue with tan markings like unto black and tan dogs.

Housing.—There are two forms of housing, outdoor and indoor. In the former the hutches are ranged in stacks out of doors, under a roof of tarred felt or corrugated iron; in the latter, a shed or properly built rabbitry is used for housing the hutches. The latter form is much the best if full attention is paid to the ventilation. The outside of all hutches should be painted. The floors should be very firmly and closely built, all joints should be well puttied, and the floors then tarred to prevent the moisture soaking through. Where a large number of rabbits are kept it is necessary to stack the hutches, and when this is done the lowest tier should be at least 18 inches off the floor or ground. Bricks or posts may be used for this purpose, but they should be covered with tin to prevent rats and mice getting into the hutches. When fixing hutches it is wise to let them slant a little to the back. This will keep the moisture from spreading all over the hutches and facilitate cleaning operations. Outdoor hutches should also be protected with shutters, which may be fixed with hinges, or held in position with bolts or Laton fasteners. Hutches for single rabbits should be about a 6 ft. square. Breeding hutches should be from 3 ft. 6 in. to 4 ft. 6 in. in length according to the size of the variety kept. Lops, Belgian Hares, and Flemish need the largest size. These hutches should be fitted with a door at either end, the two meeting in the middle, or the whole of the front may be made to open. In the larger sized hutches the double doors are much to be preferred. The fronts of all hutches should be of wood for the bottom half, and fine-mesh wire netting for the upper half. Separate breeding compartments are not advisable. The does usually make their nests in one of the corners, and if an open hutch is used one can easily and quickly examine the young, if such is needed. If cash is short, most excellent hutches can be made out of strong cases which may be bought from drapers, ironmongers, or provision dealers. Rabbits are inclined to gnaw the projecting points of woodwork in their hutches, but if it is occasionally brushed over with paraffin oil there will not be much trouble in this direction.

Feeding.—Rabbits need feeding at least twice a day—morning and night, and if convenient a third meal at mid-day will do much good to suckling does and

growing young stock. To keep them in good health and condition, variety and change of food is needed. The dietary should consist of good clean sound oats, wheat, bran, pollard, barley-meal, hay, green food and roots. In the summer time ordinary pet rabbits will do well upon a handful of bran, a few oats, and a handful of green food in the morning, with hay and green food at night, and the night feed should be a generous one. In the winter, oats, bran, wheat, with hay and roots, such as carrots or swedes, may be given. When fattening, barley meal and pollard mixed into a crumbly mass should be given morning and night in addition to other foods.

High-class exhibition stock will require more careful feeding. The morning meal should consist of oats and bran, wheat and bran, or bran and pollard, with a little hay and green food; at mid-day a handful of green food should be given; at night a plentiful supply of hay should be given, some green food or roots according to the season of the year, whilst the more substantial part of the meal may be wheat or oats, or a mash made of pollard, bran, and barley meal mixed in the proportion of two-fifths of each of the former to one-fifth of the barley meal. When does are suckling young a dish of bread and milk given in the morning will prove most beneficial. Meadow grass, clover, lucerne, chicory, green peas, green wheat, sow thistle, dandelion, groundsel, chickweed, lettuce, cabbage, cauliflower leaves, celery tops, carrot tops, pea and bean haulm, in fact any ordinary domestic green vegetable or garden refuse will be welcomed by bunny.

No hard and fast rule can be laid down as to how much food a rabbit should eat. Rabbits, like human beings, vary in their needs. The small breeds must be fed with a careful hand, the larger ones more generously. Experience will soon teach how much food is needed either for single specimens, breeding does, or a hutch full of young growing stock. A pan of clean fresh water should be given every morning.

General Management.—The hutches should be bedded with sawdust or finely ground peat moss to the depth of one or one and a half inches, and this should be covered with soft straw or hay. When a number of rabbits are kept together the hutches should be cleaned out every day, single hutches twice or thrice a week. It is not necessary to remove the whole of the bedding, but only those portions which are soiled. Once a week the whole should be removed, and the floors of the hutches thoroughly scraped and brushed.

Exhibition stock will require grooming every day. The coats should be brushed with a fairly soft brush, and then be rubbed over with a wisp of hay or a dry duster. When lifting rabbits, grasp them boldly in the middle of the back, and place one hand underneath to share the weight. If lifted by the ears, the left hand should hold the ears whilst the right hand should be placed under the hindquarters to support the weight.

The small varieties may be bred with when six or seven months, but the larger breeds should not be allowed to do so until they are eight or ten months old, that is if strong healthy progeny are desired. Early breeding, if persisted in, shortens the lives of the breeding stock and weakens the progeny. The stud buck should be kept in a hutch by himself, and does that are to be mated should be placed in his hutch. Never put the buck into the hutch of the doe. The period of gestation is thirty days. Sometimes does may kindle a day before, or a day or two later. About a week before the young make their appearance the doe will be seen carrying bits of hay and straw about the hutch, and tearing the fur from her chest. It is not wise to interfere with the young unless the doe is of a very kind and friendly disposition. A hasty glance may be taken whilst the doe is feeding, or you may remove her from the hutch for a moment, but great care is needed not to disturb the nest. Just pull the edge of it back, look quickly to see if the young are all right, and then place the nest edge back as you found it. Should there be a dead youngster in the nest remove it. If all goes on well the youngsters will begin peeping out of the nest at the end of a fortnight, and at three weeks will be found nibbling at their mother's provender. At five weeks they may be removed, but if they are valuable, the longer you have them with the

doe the stronger and finer they will be. At nine weeks they should be taken away so as to give the doe time to recuperate before she is again mated. The young may be kept together until three months old, when the sexes should be divided. As the bucks approach breeding age they will need separate hutches, or they will fight and damage each other.

COMMON ILLNESSES.

Snuffles.—Cause: A parasite which invades the nasal passages. Highly contagious. Commonest in debilitated stock kept under damp, insanitary surroundings. Symptoms: Loss of appetite, dullness. A peculiar sneezing and coughing accompanied by profuse nasal discharge and salivation, which wets the chest and feet; often mistaken for a common cold. Treatment: Isolate the rabbit and disinfect the hutch. As the disease is almost incurable, destroy all affected animals of no great value. Feed very liberally on bread and milk, corn, etc. Blow powdered borax up the nostrils, or drop in a few drops of equal parts of eucalyptus, oil and glycerine twice daily.

Diarrhoea.—Causes: Poisoning due to giving too great a quantity continuously of one kind of green food; indigestion from unsuitable food; a too sudden change of dietary, heated (fermented) food, etc. Treatment: Change the dietary. Give meadow grass if possible. A feed of shepherd's purse, or some water to drink, sometimes checks active symptoms. In young rabbits try feeding on bread and milk only for a few days.

Fleas.—These pests may be kept in check by constant dustings of insect powder into the fur, and attention to securing thorough cleanliness.

CAVIES.

A quarter of a century since the word Cavy was not at all common. In those days people talked of Guinea-pigs, but since the little squeaker of our boyhoods' days was elevated into the position of a show animal it has rejoined in the more high sounding and dignified appellation of Cavy. It is descended from the wild *Cavia porcellus* ("Restless Cavy"), and is a native of South America. Cavies make most pleasing and attractive pets for children, as they are most docile and tractable. Seldom, indeed, does one hear of a Cavy proving savage or vicious. During the summer months they may be given a hut, with a long wired run which may be placed in a convenient spot on the lawn, being moved to a fresh spot each day. They will clip the grass as close as any mowing machine, whilst their manure acts beneficially as a fertiliser. When out on the lawn they should be given clean fresh water to drink at least twice a day, and a few oats once a day. Their bed should consist of hay or soft straw. Common Guinea-pigs may be bought when young at from 1s. to 2s. 6d. each. Show specimens fetch anything from 5s. or 7s. to 25s.

Varieties.—There are three varieties cultivated by British fanciers:—(1) *Peruvian* or Long-haired: points—size, shape, length, density and fineness of coat, colour, the coat should completely envelope the body and hide the head; these trees have an extra good specimen reached the wonderful length of 18 inches from the root to the end of the hair; colours—black, blue, fawn, cream, white, and agouti, with combinations of these in bi-coloured and tri-coloured pigs. (2) *Abyssinians*: points—size, shape, colour, harshness of coat, rosetting; the coat should be like put-wire, about 1½ inches in length, and full of well-defined rosettes; colours—black, red, white, agouti, tortoiseshell, tortoiseshell and white, and other bi-coloured and tri-coloured combinations. (3) *English*, or Smooth-haired: points—size, shape, colour, fineness of coat, and markings. Sub-varieties:—(1) *Pointis*: silver and gold, the ground colours are silver grey and rich golden red intermixed with black ticking. (2) *Brindles*: intermixed black and red, hair for hair, being the standard of perfection. (3) *Cinnamon*: very light fawn or buff with faint ticking. (4) *Dutch*: marked like the Dutch rabbits; colours—agouti, black, red. (5) *Himalayan*: white with black noses, ears, and feet. (6) *Sels*: black, blue, chocolate, cream, red, white. (7) *Tortoiseshell*, bi-

coloured, red and black in distinct patches. (8) Tortoise-shell and white, tri-coloured, red black, and white in distinct patches. (9) Tri-colours; agouti fawn and white, chocolate fawn and white, and other combinations of above colours.

Housing.—If a stable or an outbuilding with an impervious floor is available, guinea-pigs may be kept in pens separated by boards, about a foot high, over which they will not climb. They should be given warm boxes to lie in. If kept in hutchies no division or sleeping box is necessary. The fronts may be covered with 4-inch mesh wire netting, which need not be carried more than about a foot up. It is, however, necessary to afford perfect protection from the possible onslaught of rats, cats, dogs, &c. Minimum size of pen or hutch for a trio and their unweaned progeny: 3 ft. long, 18 in. wide; allow an extra foot in length and 3 in. in width for every extra cavy. Outdoor pens on the comp and run principle, but so constructed that vermin cannot burrow their way in, form suitable abodes if placed in a sheltered and sunny position. They should be stood on a concrete floor if intended to remain as permanencies. The general principles of housing given in the chapter on rabbits are equally suitable in the management of cavies.

Breeding.—Cavies are gregarious, and live in communities of a boar and several sows. Two strange adult boars must be kept apart; but an adult will generally accept the company of, and settle down with, small boars of three weeks or a month old. Sows resent the introduction of strange members of their own sex to their pen.

When breeding high-class exhibition stock, the usual practice is to run one boar with three or four sows, and when the sows are seen to be in young to remove the boar to a hutch by himself. The period of gestation is seventy days. The young are born fully haired, and begin to run about and feed almost at once. It is not safe to leave the young with their mother after they are six weeks old, as there are instances on record of their breeding at this early age. When the young are removed from the breeding pen the sexes must be divided. It is advisable to let sows have a hutch to themselves at the time of kindling so as to be able to keep correct pedigrees, but if this is not essential then the sows may remain in the breeding pen. They will not interfere with each other's progeny, but on the contrary the sows will all suckle the young indiscriminately. As soon as the young are taken away from the sow the boar may be introduced again.

Feeding.—The general principles given in the chapter on rabbits are applicable to the feeding of cavies.

COMMON AILMENTS.

Cavies are singularly free from all kinds of diseases if housed and fed in a suitable manner. There are two diseases that attack them—consumption and dropsy. We have never heard of anyone curing the former, and very seldom the latter.

Skin Troubles.—When fed on a diet that is too dry, or too heating, Cavies are apt to suffer from irritation of the skin, and they commence to bite themselves and thus spoil their career as show specimens. As soon as a Cavy is seen to be biting itself a sprinkling of flowers of sulphur should be mixed in its meal mash, all dry corn should be removed from its dietary and bread and milk substituted, and in this a pinch of carbonate of magnesia may be mixed. If a sore should appear anywhere on the skin it should be washed each morning with warm water in which a few drops of Jeyes' Fluid has been sprinkled; it should then be dried carefully, and touched with a little zinc ointment.

Vermin.—If their hutches are kept scrupulously clean and their bodies groomed regularly each day, no vermin will ever be found upon Cavies, unless they come in contact with other Cavies, or boxes, which have been infected with either lice or fleas. Cavies sent away to prospective buyers are sometimes put into hutches that are not quite clean, and sometimes at shows fleas or lice are picked up. The safest and quickest remedy is to mix a little of Jeyes' Fluid in good water, dip a sponge in it, and give the Cavy a good rub over with the sponge; dry the coat with the

sponge and a dry duster. One dressing is sometimes enough, but there are occasions when the sponging will have to be repeated for several days.

MICE.

Origin.—Fancy mice are descended from the common grey house mouse (*Mus musculus*). They may cost from sixpence to a sovereign or more per pair according to colour, strain, and individual quality. The males only make an offensive smell.

Varieties.—Fancy mice may be divided into the following more or less well-defined varieties: (1) Agouti (wild colour); (2) Sable; (3) Black and tan; (4) Chinchon; (5) Self black; (6) Self chocolate; (7) Self red or yellow; (8) Albino (the "white mouse"); (9) Blue; (10) Lilac; (11) Silver; (12) Cream; (13) Dutch-marked; (14) Broken or spotted; (15) Black-eyed white; (16) Variegated; (17) Even-marked.

Japanese waltzing mice are thought to owe their peculiar habit of spinning round after the tail until exhausted to a diseased or malformed condition of the auditory labyrinth.

Egyptian Spiny Mice (*Acomys cahirrensis*) are sometimes bred in captivity in this country.

Housing.—Mice thrive if kept in pairs in the ordinary flat dealers' cage if a sufficiently large size (12 in.) is selected. These cages will not stack. A nice commercial cage (22, 62) in which the animals can be watched has a glass front, and the nest-boxes in an upper story. Home-made cages may be made from small boxes, air being obtained through a hole cut in the lid and covered with perforated zinc, a view of the animals being ensured through another hole cut in the front and covered with a sheet of glass—a cleaned photographic negative makes a good window. Mouse cages require careful construction, as the animals gnaw wooden projections. A little paraffin oil brushed on the wood helps to prevent this. Where several mice are kept together (such as a buck and two or three does) a large cage with a separate nest for each animal should be provided. Damp is fatal to these animals.

Feeding.—Feed once or twice daily. As stock food mix equal quantities of canary seed, millet seed, and oats, and give about a small teaspoonful per head daily on the floor of the cage. In addition, a piece of bread soaked in milk the size of a walnut, or as a change a little soaked dog food. The pan must be kept scrupulously clean. Dry bread or biscuit crumbs give variety to the dietary now and then.

A little vegetable food, such as flowering and seedling grass heads, groundsel, dandelion, or lettuce leaves, or a tiny piece of apple, carrot, swede, or mangold, may be given daily. No sour or decomposing fragments of moist food must be left about the cages.

General Management.—The cages must be kept thickly covered with dry sawdust. Some fanciers sprinkle Sanitas over the sawdust before use, or mix equal parts of Sanitas sawdust and ordinary sawdust to mitigate the unpleasant smell made by the bucks. If the cages are kept scrupulously clean, and as few bucks as possible retained, then the presence of mice in a building need not be unduly obvious. The contents of the cages should be changed at least three times a week, care being taken to scrape well into the corners. The nest should be changed once or twice a week.

Mice should always be kept in couples or several together, as one animal does not thrive alone. Males brought up together from birth will live contentedly; but two adult bucks will fight and injure one another if an attempt is made to keep them together.

Mice breed very early and will produce from four to six litters in a year. The period of gestation is 20 days, and the young will probably average about five in a litter. The buck and doe may be left together always; or if it is desired to keep only one buck and several does the animals can all run together, each doe being removed to a separate cage when she is seen to be in young. The doe will make her own nest out of clean hay provided a few days before the litter is expected. The young are born blind and naked. About five or six days after birth the young can be looked at, the prettiest selected to rear, and the remainder destroyed.

The young should be taken away from the mother and the sexes separated when they are four weeks old. It is not advisable to allow them to breed until they are three or four months old, though they will do so much sooner when well fed.

Mice may be lifted by grasping the tail firmly about half way up. No attempt must be made to pick them up by the extreme tip.

COMMON AILMENTS.

Skin Trouble.—Symptoms: Small irritating pustules form on the skin and are quickly scratched into sores. Cause: Too heating a class of food. Treatment: Rub in sulphur ointment (flowers of sulphur mixed with vaseline). Sprinkle a pinch of sulphur on the bread and milk three times a week, or dissolve a little Epsom salts in water and give to drink, withholding all moist food. Increase the daily allowance of grass and vegetable food.

Mice occasionally die of fits, or are carried off in a few hours by pneumonia. Nothing can be done for a sick patient beyond keeping it warm and dry.

RATS.

Origin.—Some doubt exists as to whether fancy rats are the descendants of the Brown Rat (*Rattus norvegicus*) or the old English Black Rat (*Mus rattus*). Young white or piebald rats can usually be purchased from an animal dealer for about 6d. apiece, and the females, tamed while young, make interesting and attractive pets. The males have an unpleasant smell. Sexes called buck and doe.

Varieties.—Fanciers divide rats into the following varieties: (1) The Pink-eyed Albino (which is most admired when pure white and free from a yellow tinge); (2) Agouti (the grey or brown wild colour, with or without a white ventral surface); (3) Self Black; (4) the Hooded Rat (which is white with black or agouti head, shoulders, forelegs and dorsal stripe); (5) the "Irish" (which is black with a more or less white ventral surface); (6) Self Fawn or Yellow (specimens of which have recently come into the possession of several breeders).

Housing.—A cube sugar-box or an empty tea-chest makes a most suitable abode. The front should be closed in with a frame covered with 1-in. mesh wire-netting, and should be hinged to form a door. Inside this it is convenient to have a thin board of hard wood, 3 in. or 4 in. high, run across the front of the hutch, and let into grooves at each side, to prevent the sawdust, husks, etc., from being scattered about. A small lidded box, with a hole bored in one end, should be placed inside the hutch as a sleeping-box. Bird travelling box-cages, of parrot size, procurable at most dealers, also make nice small, if not very convenient, cages for one pet rat.

Feeding.—Rats thrive best on a great variety of food, which must not be of too heating a character. Bread and milk, soaked (dog food occasionally, boiled rice, or, in fact, any plain farinaceous pudding, are suitable and appreciated, and if a little moist food of this class is given daily together with some vegetable food the animals will require no water.

A heavy non-upsettable feeding-pot must be provided, and no more food given than is eaten up at once, as the remainder will be carried away to decompose in the nest. Grass heads in flower and seed, dandelion, chicory, lettuce leaves, etc., in summer, and a slice of apple, carrot, mangold, swede or parsnip in winter, will provide the necessary vegetable food. One or two tablespoonfuls of grain should be thrown into the hutch daily. A mixture made of equal parts of wheat, maize and oats is useful as a stock mixture; and a second made of equal parts of canary seed, hemp seed, sunflower seed, linseed, buckwheat, millet and oat can be made and given occasionally as a change. Feed once or twice daily.

General Management.—Dry sawdust should be sprinkled on the floor of the hutch, and the nest-box filled with hay when the hutch is cleaned out. This

should be at least twice weekly during the winter, and three times weekly during the summer months.

Rats are very prolific. The period of gestation is about twenty-eight days, and the animals will commence to breed at five or six months old, or even earlier. The number of young at a birth varies from four to twelve (nineteen is not unknown); in favourable circumstances a female may have from four to six litters in the year. The young are born blind and naked. The animals may be palmed, or one buck kept successively with several does for a period not exceeding three weeks.

No particular attention is required when the young are due beyond seeing that the nest-box is free from stale food, and provided with clean soft hay. The parents may be left together; but the nest should not be disturbed nor the young examined until they are at least a week old. The young can be weaned when six weeks old by removal to a new hutch. It is advisable at this stage to separate the sexes, as the bucks will then live peacefully together if undisturbed until fully grown.

As regards ailments, etc., treat skin trouble as recommended under this heading for Mice. Fleas will not give trouble if the animals are kept in clean surroundings and prevented from mixing with flea-infested specimens.

SQUIRRELS.

Squirrels are very generally distributed over the whole of the habitable world with the exception of the Australian region and Madagascar. Of the sixty or seventy species known, there are about a dozen which can be kept in a state of captivity, provided that proper accommodation is provided for them.

Varieties.—Even foreign squirrels are not expensive pets: Chipmunks cost from 10s. per pair; Flying Squirrels from 15s.; Grey Squirrels from 20s.; Dorsal Squirrels from 25s.; Prevost's Squirrel from 40s.; the Common Squirrel only about 4s. 6d. or 5s. The most expensive are the Malabar Squirrel, which cost from £3 to £5 per pair.

Common Squirrel (*Sciurus vulgaris*).—In colour this species is brownish-red, the chest and ventral parts being a drab-white. During the late autumn and winter months the ears are densely tufted with hair, but during the spring and summer this growth gradually disappears, until about the end of June the ear-tips are almost naked. When born they are both naked and blind, and when the fur makes its appearance is the best time to take them if hand-reared specimens are required. Adult caught squirrels seldom get tame or even reconciled to captivity, and after a longer or shorter period usually pine away unless kept in large enclosures.

Grey Squirrel (*Sciurus carolinensis*).—A very pretty and attractive animal of a silver grey colour; but there is considerable variation in the coloration of all these animals, and some grey squirrels are nearly black and others nearly as red as our common species. They are the cheekiest and most confiding of all, and as pets are pre-eminent.

American Flying Squirrel (*Sciuropterus hudsonius*).—This is a dusky brown tint above and creamy-white beneath. It thrives well in captivity, and gets tame more quickly than any of the other kinds.

Dorsal Squirrel (*Sciurus dorsalis*).—A handsome animal, brownish-red above and whitish-fawn beneath; but like the others is very variable in coloration. Prevost's Squirrel is an allied form.

Malabar Squirrel.—A very large and beautiful creature of rich dark chestnut colour above, with cream underparts; it is about 2 feet in length.

Chipmunk (*Tamias striatus*).—This species belongs to the Ground Squirrels. It is smaller than its relations and prettily striped with black and white on a ground colour of black and fawn.

Indian Palm Squirrel is not so frequently imported as the other foreign squirrels owing to its capture being attended with some amount of difficulty, but it is a very handsome creature, with beautiful

markings and a delightfully soft fur. It gets tame very quickly but is somewhat delicate in confinement.

Any of the above-named squirrels are well worth the attention of any pet keeper, as they are much more interesting to keep and show one's friends than the common European example. They are all amusing and intelligent pets, and when tame are really delightful little companions when let out in a room. It is better not to take them out of doors where trees abound in case the love of freedom asserts itself too strongly and they get out of bounds.

Cages.—The cage for squirrels ought to be at least 4 feet square and solidly put together of tin, material, all projecting edges being protected with tin, as these animals, being true rogues, have a knack of gnawing their way out of a cage. The wire front is best of half-inch mesh galvanised wire netting. A retiring-box about a foot square should be attached to the back of the cage near the top just below the roof. This box should be accessible from the outside, by means of a small door cut in the frame of the main cage, so that it can be quickly got at to clean out when necessary and put in a new one. It is a mistake to have the doors of a squirrel's cage too large, as these animals are very lively and quick in their movements, and would slip through the moment the door was opened unless it were only just big enough to admit the arm. The floor of the cage should be strewn with fresh sawdust and on top of this a layer of hay or straw; straw is the better of the two, as it encourages insects, and once these have made a foothold it is difficult to get rid of them. The cage for the ground squirrel need not be so large, and the hay for the sleeping box should be as fine and soft as possible, for the Chipmunk spends most of its time curled up therein. Those species other than the Chipmunk ought to have part of a tree branch fixed diagonally in their cage from a lower corner to an opposite upper one so that they can play about upon it. Earthenware food and water vessels are better than iron or metal ones, as they are more quickly cleaned, merely requiring to be dipped in hot water and wiped dry with a towel, besides being free from the likelihood of rust; the only advantage of a metal food dish is that it is less liable to be overturned. The cage must be cleaned out once a day and not less than every week should be scrubbed over with boiling water and some brand of disinfectant soap. If this be regularly done the interior of the cage will always be clean and free from any objectionable odour.

The Grey Squirrel is quite hardy and can be kept out of doors all the year round if it has a large enclosure or aviary to get plenty of exercise in, and will breed if a pair have the place entirely to themselves. As they are extremely jealous and pugnacious in disposition, different species cannot be kept together; if they were, it would be nothing less than one continual round of quarrelling, often resulting in the infliction of severe injuries on one another.

Feeding and Management.—Nuts form the principal portion of the dietary and are an absolute necessity. Almost any kinds are relished, but Brazils and filberts seem the greatest favourites. Plenty of fresh water is necessary, as squirrels drink a little and often. The fruits may be oranges, dates, apples, pears and grapes. Grain food in the shape of Indian corn and oats forms an agreeable supplementary diet. Carrots and greens are also useful as a change. Bread is also useful but should not be given in the form of bread and milk, but is better if dry or merely dipped in milk sufficiently to just moisten the outside. The Dorsal Squirrel is very fond of grapes, and as these can be got very cleanly at the grocery, the extra cost of feeding entailed by giving these does not make an undue burden on the pocket, as it only amounts to a few pence per week. Although nuts are the principal form of food, squirrels ought not to be fed solely or for any length of time upon them without the addition of other forms of diet, as internal troubles arise if this be done; change of food and variety is always beneficial. Inflammation of the lungs appears to be the prevailing illness which is fatal to the foreign species of squirrels, and unfortunately there is no cure and nothing can be done to relieve the sufferer, which as a

rule only lives a very few days after being seized with this complaint. They also suffer from worms, which can be got rid of by the use of the time honoured *areca nut*. As the incisors grow rather rapidly some coconut shell or other similarly hard substance should be provided for them to gnaw at to keep their teeth in proper trim.

MONKEYS.

As pets monkeys have always had a peculiar fascination for most people, although it must be admitted that usually the anticipation has proved more delightful than the realisation, the aftermath—as it were—of the desire being a trying period and the time that these pets were kept a continual round of worry and vexation, often culminating in disagreeable interviews with the neighbours and estrangements in the household. This has often been due entirely to ignorance and carelessness; ignorance—in not knowing how properly to care for and look after the animal, and carelessness—in omitting to do some proper thing at some proper time or in some proper manner. As an example—a cage for a monkey—using the word in a wide sense—should always be fastened with either a lock and key or a padlock; the use of an ordinary turn-button or a screw-hook and eye to a cage being nothing short of criminal. A monkey man, if it gains its freedom unobserved, do an enormous amount of damage before its absence is detected and it can be recaptured.

Speaking generally monkeys are all tameable, but are very often extremely capricious in their likes and dislikes for their human friends. Occasionally one that is good-tempered will take a dislike to some person, and will consider it good fun to scratch and bite the fingers of that individual if he (or she) is imprudent or forgetful enough to place them within reach. Some species are endowed with a preternatural cunning, and it takes all the time of their owner to guard against some unpleasant contrivance. One of these monkeys will get an idea into its mind, and weeks may go by before a favourable opportunity occurs to mature it; however, when the chance comes, the long period of waiting is fully made up for, and the gloe of the monkey at circumventing the astuteness of its guardian is most marked, and its pleasure is shown in a vivid manner, chuckling with delight until retribution comes, when poor "Jacko" is transformed into a very forlorn and woe-begone animal.

Usually it is the ladies of the household who object to monkeys, and when one is suggested as a pet, draw very vividly upon their imaginations as to their mischievousness and the amount of damage they are likely to cause. They are often right, too, for naturally, if a monkey is to be allowed the run of the house, such things as the breaking of choice ornaments and pieces of china, and the picking up to bits of antimacassars or portions of delicate needlework, are almost sure to happen. Like many other creatures, monkeys will follow the bent of their own inclinations, and are ever on the alert to "do those things which they ought not to do," and very seldom "do those things that they ought to do," so that they often make their presence known in an unacceptable manner.

When choosing a monkey as a pet, a male should be selected, as the females are often very objectionable besides being less hardy, and for obvious reasons, except for scientific purposes, the latter ought to be separately caged, if kept at all. Care likewise should be taken to obtain a young animal, as they get morose and treacherous as age creeps on them. A monkey which has been kept as a tame pet for years will prove no exception to this rule. When people find that their pet is getting sullen, they generally part with him for a mere song, and the individual who unfortunately speculates in one of these is generally disgusted beyond hope of cure. Cheap monkeys are nearly always either old or else ailing, and it is far better to go to a respectable dealer and pay a reasonable sum for a healthy young animal than to waste money in buying such specimens that are either morose or treacherous.

We have often been asked—"Can monkeys be taught to perform tricks?" Well, the answer is that

that depends in a very great measure on the patience and capabilities of the instructor; whatever tricks are taught, perfect likeness must be maintained the whole time the lessons are going on. A monkey should never be struck, even if it bites, as a blow is never forgotten by one of these creatures; kindness is the great secret with these animals. Given a good healthy young monkey, there are few more interesting and amusing pets.

Varieties.—The most frequently imported monkeys are the Guenons and the Macaques. The Guenons, from their usually rich coloration and their affectionate and interesting ways, are favourites among those people who are making their first essays in monkey-keeping. They are all treated in a similar manner and it is usually either a question of price or else of a personal predilection regarding the colour and appearance of one of the species which decides the choice in the prospective owner's mind. The two species most commonly met with are the Lesser White-nosed Guenon and the Green Guenon.

Lesser White-nosed Guenon (*Cercopithecus paterfamilias*).—This is a very gentle and active monkey, displaying great affection to those who take notice of it and treat it kindly. Some individuals dislike being handled or in any way being interfered with. The head and upper parts of the body and tail are olive-green, speckled with yellow; the underparts are white, as are the whiskers and beard; the face is black; the lower portion of the nose and the upper part of the top lip are white—hence the popular name; there is a black line across the forehead which encircles the crown. The usual price for this monkey is from 5s. upwards.

Green Guenon (*Cercopithecus callitrichus*).—A species very rich in coloration; the head, body, and the outer surface of the limbs are a very beautiful yellowish-green; the hairs being annulated with yellow and black; the under parts of the body, inner surface of the limbs and the throat, white tinged with yellow along the median line. There is an orange tuft at the tip of the tail. From 5s. to 10s. is the price charged for this species.

Macaques.—Of these the commonest are the Bengal Macaque (*Macacus ferus*) and the Bonnet Macaque (*M. sinicus*). The former is a greyish-brown colour with a whitish-white underparts; young examples may be distinguished from their elders by the flesh-colour of the callosities, which reddens with age. The Bonnet Macaque is olivaceous-brown on the body; the exterior surfaces of the limbs are greyish. The coat of either is from 5s. to 10s.

Marmosets.—Some dealers advertise a small "monkey that will go in a pint pot"; a description they give to the Marmoset, the body of which is a trifle smaller than that of a rat. Being extremely quiet and quaint, it is preferred by some people, particularly those of the weaker sex, to the larger monkeys, as the soft woolly fur makes it much resemble a young kitten. The fur is delicately soft and bushy, and is ornamented with blackish-brown stripes upon a ground of deep tawn. The tail is annulated with black and white; the head is black and adorned with two tufts of white hair, one over each ear. Marmosets cost about 15s. Insects and fruit form the diet, both of which are plentiful enough during the summer but in the winter are difficult to maintain a constant supply of. It hardly matters what insects are given, caterpillars (not the hairy kinds), flies, moths, butterflies, mealworms, cockroaches; spiders are also relished. The fruit should be quite ripe. Bread and milk, if not sloppy, may also be given occasionally.

Capuchins.—The Capuchins of South America are analogous to the Guenons of Africa, and the one most commonly imported is the Brown Capuchin, which is a very docile and affectionate monkey of a reddish-brown colour. It is also the hardest as well as the cheapest of the Capuchins, costing, as a rule about 4s. Too liberal a supply of food is harmful. To a great extent these monkeys are flesh-feeders, and a newly-wild marmoset or a newly-bred Capuchin can be given. If it absolutely fresh, are also greatly relished. The Capuchins are more delicate than the Guenons and ought to be kept in a warm room.

Feeding and Management.—The details of feeding Mangabeys are in every respect the same as for the Guenons, but the Macaques are more voracious than their relations and a more liberal supply of food must be given; boiled rice, odd bits of bread and vegetables (carrots, potatoes and onions), pea-flour and meat may be mixed into a kind of pudding and a tinfoil given each day, morning and night; nuts, peas, maize, raw carrots, apples (sliced) are all relished. Dates, figs and grapes may be given as luxuries.

All the Guenons are noted for the extreme development of the cheek-pouches, which, when full, give a very peculiar appearance to the face of the animal. A Guenon on being offered a nut or a portion of fruit from a large bag of food will pouch whatever is given to him until the pouches are full or else that the person ceases giving, and will not commence eating before all chances of receiving further supplies are lost. Most of the Guenons are fairly long-lived in captivity, their span of life averaging some seven or eight years, but instances are known of some individuals having lived double that number of years. They are mostly good-tempered one towards another when several are kept in one cage. Of the two species named the Green is the hardier and it bears our climate very well, rarely, if ever, ailing anything. Both are very playful and engaging during their youth, but, like nearly all other monkeys, become vicious and morose as they get old. If the cage is small it is a good thing to let the monkey out once or twice a day for exercise, but the doors and windows of the room should be kept shut and small ornaments removed, as the long tail of a Guenon is a very awkward weapon when flourished about, and would easily knock a valuable vase off a bracket or the mantelpiece in spite of the monkey trying to be most careful when jumping about. If the cage is long enough at a time for a monkey to be away from its cage, and at such a time it should never be left alone or out of sight for a single instant, as, however quiet and inoffensive it may appear when closely watched, a monkey can never be trusted not to take advantage of any opportunity that may present itself.

The Macaques are not so suitable for the average named pet-keeper as the Guenons, as although they are interesting in many ways and serve to widen one's experience of monkeys, they cannot be relied upon. Their temper and equanimity may be perfect one moment, and the next they are transformed into veritable little fiends. No monkey likes being teased, but these are nearly as resentful as the Baboons, and a bite from them, if they get near enough to their aggressor, is a serious matter. Another reason—more important in many ways—is that they are not suitable pets where young children are, as some of their actions might not be approved. When quite young they are very amusing and can be taught many little tricks—in fact, the performing monkeys seen in circuses are usually trained Macaques.

Cages.—The cage for an ordinary monkey should be at least 4 feet or 5 feet long and correspondingly high and broad. A door should be placed at each end to enable all parts of the interior readily accessible when the cage requires cleaning. Stout galvanised wire netting of 1/4 in. mesh is as good as anything for the front, with a wooden moulding strip nailed over the edges to finish off and improve the general appearance. The internal fittings need not be either complicated or costly; merely two or three food dishes, a sleeping perch, and a looking glass framed in stout wood. If the cage is intended for Marmosets, a swinging-box is an advantage. It can be placed at the top of the cage, a stout bough of a tree connecting it with the floor and thus giving the inmates of the cage a means of getting to the retiring chamber, which should be filled with sweet hay. Many people who keep monkeys cover the floor of the cage with sawdust, and others use only hay; but the latter is by no means the cleaner every day and the cage floor thoroughly brushed down, and once a week scrubbed out with a strong mixture of soda and water.

DORMICE.

Amongst the smaller mammals the different kinds of European Dormice are great favourites not only with children but also with "grown-ups."

Varieties.—There are three species which may, as a rule, be readily obtained from dealers of live stock. These are the Common Dormouse (*Muscardinus*), the Squirrel-tailed Dormouse (*Glis esculentus*) and the Garden Dormouse (*Eliomys quercinus*). All are within reach of the humblest pet-keeper, the first-named costing about 2s. 6d. and the others from 4s. 6d. to 10s. 6d. per pair, according to the number in the market. The Common Dormouse is too well-known to need any description. The Squirrel-tailed Dormouse is a very pretty little creature; the coloration is ash-grey above and white beneath. It is considerably larger than its common relation, being about 6 inches in length without the tail, which is another 5 inches. The Garden Dormouse is not quite so big, being only 8 or 9 inches in total length, of which the tail is between 3 and 4. The colour is brownish rather than ash above, with white underparts; the eyes are ringed with black, which is extended as a stripe below and behind the ears; the tail is tipped with black above and white beneath.

Cages.—Most people make the mistake of keeping dormice in cages which are far too small. A cage for the common species or glt not to be less than 18 inches to 24 inches long, and proportionately high and broad, whilst for the Squirrel-tailed Dormouse it should not be less than 5 feet long by 4 feet high and 3 inches wide from back to front. The latter species, when awake, is a remarkably active creature and is constantly on the move, jumping and running about all over its cage and is quite as lively as the animal from which it takes its popular name. All the Dormice are arboreal in their habits, and provision ought to be made for this; in the small-size cage one small tree branch is sufficient, but in the one for the larger species two or even three may be necessary. The sleeping-box—a most important adjunct for these little mammals—which often spend nearly six out of the twelve months of the year asleep—should be placed at the top of the cage in such a position that it can be readily got at to inspect the interior now and again without disturbing the inmates; this is best done by means of a door in the side or roof of the main cage which opens directly into the sleeping-box. The floor of the cage should be covered with pine sawdust, this need not be thickly spread as dormice are very clean and make hardly any mess at all. The sleeping-box may have a layer of sawdust and then be loosely filled with hay, moss, and wadding. Access to the box is given by having one of the branches so arranged that it leads from the floor to the entrance. With small rodents like these which can squeeze themselves through broken-down toys, there is no necessity to use wires at all and the front of the cage may be glazed with fairly stout glass; if this be done ventilation must be provided by having a 6 inch square cut at the bottom of each side of the cage and another at the top near the centre and these covered with perforated zinc; these, of course, may be made as doors.

Feeding and Management.—Dormice should be fed regularly twice a day on bread-and-milk, nuts, biscuits and fruit. It is best to shell the nuts so as not to give the animals too much practice in nibbling in case they turned their attention to the woodwork of the cage. Hazels, walnuts, acorns and chestnuts may be freely given and the Squirrel-tails are especially fond of chestnuts. Water should be liberally supplied. If kept in a warm room and food abundantly provided the chances are very much in favour of the Dormice not hibernating, but they will get corpulent just as if they were preparing for a long winter sleep. It was in ignorance of this fact that led a pet-keeper, who had recently acquired a solitary male at the latter part of the autumn and who was not aware of the sex of his pet, besides misunderstanding the motive, carefully to prepare a very special nesting-box daintily lined with best white cotton-wool; he then anxiously awaited developments, but, like the followers of Joanna

Southcote, he watched and waited in vain! If more than one pair be kept in one cage quarrels are sure to arise, and an additional advantage in keeping only a pair of the Squirrel-tailed species is that there is every probability that they will freely produce young in a cage of the dimensions given often twice a year. Gentleness is a *virtue qua non* with all Dormice as, although pugnacious, they are extremely nervous creatures, and no one can successfully keep them who is not both gentle and patient. They get very tame and may safely be let out during the evening for a scamper round the room; they will fearlessly climb all over their owner, and jump comparatively big leaps for their size from one article of furniture to another. For young people there are very few of the smaller European animals that are more suitable as pets than these graceful creatures, not only because they are comparatively inexpensive to purchase, but also in that they are so little trouble to look after—a very important matter in such cases where there may be a tendency for the novelty of having them to wear off after a short time. Just a final word of warning; should any of my readers possess an example which commences hibernation in earnest, it should, in no circumstances, be interfered with, or roused from its winter sleep, as such would in all probability prove fatal.

LIZARDS.

Under the popular name of Lizards are classed by naturalists an extremely large number of species and varieties showing great variability, and a very wide geographical range. By the modern classification the Lizards (*Autosauri* or *Lacertiles*) include the ancient Gekkos, which are practically cosmopolitan, and the African Chameleons and several other families. The true Lizards, however, are the *Lacertidae*, and these alone number upwards of a hundred species. It is impossible here to go into the natural history of this gigantic and somewhat unwieldy family, or to point out the differences which exist: nor would it serve any good purpose to do so. All that is proposed is to refer to several species which have proved adaptable to a life of confinement and which, therefore, may be kept as pets.

Even our native Lizards are of considerable interest and some of them make pretty little pets. The Common Lizard of this country is a species with a very wide range—extending, in fact, through Northern and Central Europe and Siberia to the Saghalien Isles. To Ireland it is a specially interesting species inasmuch as it is the only reptile found in that country—another injustice to "Ould Ireland." One of the most curious and interesting things in connection with the *Lacertilla* is the capability of reproducing a tail should this organ, as it very frequently does, get broken or trampled. Naturalists do not, however, regard such a reproduction as a true tail, as it is wanting in several essentials. The marvellous regenerative power is centred in certain cells found in a transverse septum of cartilage and is retained throughout the animal's life. An excellent example of this tail-brittleness is found in the common, useful, and much persecuted Slow-worm (*Anguis fragilis*), which is in reality a legless Lizard and not a Snake as commonly thought, and which through ignorance is killed as being harmful to man, while in reality it is not merely incapable of inflicting harm but is a most useful reptile, destroying vast quantities of insects and slugs, and therefore should be preserved rather than killed.

Varieties.—Some of the common species will do very well in captivity—the Eyed-Lizard for example—and moreover live for ten years and more; others, like the exquisitely coloured Green or Emerald Lizard found in Jersey do not live very long. Most of these reptiles when kept in captivity become remarkably tame and exhibit in some cases an intelligence that one does not as a rule associate with the Reptiles generally.

Lizards, generally speaking, lay white or creamy eggs, having either a hard or a tough soft shell as in our native *Lacerta vivipara* and the exotic Chameleons.

With some species the eggs are not laid until the embryos are absolutely ready to emerge, while yet others—*L. vivipara* and *Anguis fragilis* for instance, two of our native Lizards—are viviparous. In those cases in which the egg containing the embryo is especially hard Nature has provided the embedded reptile with a means of freeing itself. This it does by means of a tooth-like process on the snout. We will now enumerate a few of the species that may be kept in various ways, though some little care is needed in the selection of species to live together, or at least in a case of survival of the fittest.

Blue-Tongued Lizard (*Tiliqua gigas*).—Belonging to the Skink family is a pretty but large Lizard whose chief characteristic is suggested by its popular name. An adult measures 20 inches or so, and therefore a suitable-sized apartment must be provided. Unfortunately this Lizard cannot well be kept in a room whose temperature falls below about 65 degrees. Its case should be located in a sunny place and a retreat, made of a piece of bark or of virgin cork, should be placed in one corner of its apartment. Slugs, snails, with now and again a little raw beef cut up, will be suitable food for the reptile. It should also be supplied with water and a 3-inch layer of sand should cover the apartment floor.

Common Chameleon (*Chamaeleo vulgaris*).—Quite one of the most remarkable of all the Lizards by reason of its ability to change its colour according to varying moods, to dilate its body, and to subside for so long a time without food that it was commonly asserted it lived on air. Another remarkable feature of the Chameleon is the long extensible tongue by means of which it secures its food; while yet another is the eye structure enabling it to see in every direction without moving either its head or its body. Again the long tail is prehensile. Although extremely interesting the Chameleon is somewhat troublesome to keep in winter as its quarters must be warmed. In summer this is unnecessary. The case in which it is kept should have a warm and sunny aspect and at one corner a slight shelter should be afforded the timid reptiles. The food best suited consists of cockroaches, and other small insects, including flies. In size this Lizard measures when full-grown about 1 foot. It should not be kept with other species; and although this reptile will not take water from a vessel it will do so if the fern-case in which it is kept be gently sprayed.

Emerald or Green Lizard (*L. viridis*).—Beautiful though this species undoubtedly is, it cannot generally speaking be recommended as one to be kept in captivity. Emerald green is the prevailing colour of the upper surface of this Lizard, which measures in the case of males 10 inches or 12 inches in length, the majority of it being tail. Beneath it is yellowish, while the throat is blue, or bluish in the case of males in the breeding season. In its native habitat it prefers rocky places. Like many other Lizards it will eat insects of various kinds (including butterflies) snails, and earthworms. It can be called a British species, as it occurs in Jersey.

Eyed-Lizard (*Lacerta ocellata*).—One of the most satisfactory species to keep in confinement, but on account of its voracity it is best placed alone in a greenhouse. After a time this species will get very tame, so tame as to take proffered food from the hand. Mice, earthworms, cockroaches, etc., may be given to this Lizard, which is some 20 inches to 24 inches long. The popular and specific name has been bestowed on account of the ocelli, or eye-spots. In colour this Lizard is green above and often exquisitely reticulated with black. Beneath it is greenish-yellow; while at the sides are numerous blue, black-edged spots, which account for its specific and popular names. The males attain a large size—2 feet and more in length, and assume their most beautiful coloration at the breeding-time. This species retires for the winter, burrowing into the soil in late autumn to emerge with the fine days of the returning spring.

Prickly Lizards.—By this name are popularly known several species which, though of good reptile as pets, are nevertheless unready to look upon by reason of the spine-like processes covering their body. They are, however, less formidable than they seem;

indeed they are classed as gentle reptiles that will bear handling with impunity. To the majority, however, they are not likely to appeal, more especially too as they are somewhat expensive. The Derbian Zonure (*Zonurus derbianus*) is one of the best of the group. Like some other Lizards this species is capable of taking long fasts. The food most acceptable to it consists of mealworms, small beetles, and grubs; while a vessel of water should be supplied in its case. As in the case of the Blue-Tongued, its case should be provided with a snug retreat; the floor of its apartment should also be covered with sand. It may be allowed to hibernate in a box or other receptacle containing leaves, but this must be kept in a room in which there is a fire the night through.

The Slow-Worms (*Anguis fragilis*).—A native species known also as the Blind-Worm. This latter name is a most inappropriate one as the species has excellent eyes. It measures from 10 inches to 1 foot or more in length, and though there is a slight tapering towards the tail it is of almost uniform thickness. On the upper surface it is brownish-grey, with a metallic sheen; beneath it is black, but the colour is variable. The young are silvery-white above with three black lines, and black beneath. Except the gravid females, these reptiles like the shade. They feed on snails, earthworms, and slugs, and hibernate in burrows in the soil. The food should be given alive.

Viviparous Lizard (*L. vivipara*).—A very variable species in which the female is larger than the male. The colour is brown or reddish above, with darker or lighter spots, and occasionally there is a dark yellow-edged band at the sides; beneath the male is orange or even red, and the female very much paler. From 6 inches to 7 inches would represent the length. The young are under 1 inch when born and are left by the parents to slift for themselves. Greenish succulent morsels are provided for them with food until they are capable of taking food similar to that given to the Eyed-Lizard. This species hibernates in autumn.

Wall Lizard (*L. muralis*).—Another very variable species which derives its popular name from the fact that it has in some of its native habitats a partiality for walls. Though resembling the Common Lizard it is 2 in. or 3 in. longer and has a fine tapering tail while that of its relative is for a greater part of its length of equal thickness. It requires similar treatment to the Common Lizard, and is very partial to garden worms. This species also occurs in the Channel Islands.

Housing, etc.—To those who can afford to purchase ready-made one of the delightful little vivaria that are on the market, the problem of how best to accommodate these Lizards which cannot be allowed the run of a warm green house, might be readily solved. Nevertheless, however, these are somewhat expensive, and it is not at all unusual for those who go in for Lizard-keeping to rig up a suitable substitute thereof out of a box, affixing thereto a thick glass front and a door made of perforated zinc. Such a home-made structure would necessarily vary as regards its dimensions with the particular species that it is desired to accommodate. So far as the species dealt with are concerned, a vivarium that would be suited to a reptile of the size of the Eyed or the Blue-Tongued Lizards might very well be 4 feet long, 2 feet high, and 24 feet wide. The bottom should be thickly strewn with small shingle or sand and a retreat at one corner should be fashioned out of cork, bark or something similar. A small tree-branch would also be a useful addition. Generally speaking the Lizards are sun-lovers and therefore the vivarium should be so situated that it gets as much as possible.

Feeding, etc.—As the favourite food of the different Lizards enumerated has been given when dealing with them specifically there is little need to refer to it specially. Still it may be as well to state that clean fresh water should be provided in a pan, for though it is not unusual for these reptiles to abstain from taking it for a long time on end, yet it is a necessity for them.

In the enumeration of species we have not included the locally distributed (in this country) Sand Lizard

(*Lacerta Agilis*), for despite every care and many trials with it, we have not found it a very suitable one for a life of captivity. It is larger and bulkier than *L. vivipara* with which it is sometimes confused and shows considerable colour-variation, the colours of both male and female being more subdued after the breeding season is passed. Vivid green is the ground-colour of the male at that time, especially on the sides, where it is also dotted with black, and has whitish eye-spots. Beneath it is yellow. The female is a combination of grey or dark brown with rows of white centred spots. This Lizard is very common in parts of Surrey and Dorset. It may be stated that those wishing to catch Lizards in their haunts should never attempt to do so by the hand. The proper way is by means of a thread-noose attached to a thin, pliant stick.

TORTOISES.

Nearly everyone in large towns is familiar with certain species of Land Tortoises which are sold by wily itinerant merchants as useful aids to the gardener, who, unless he be something of a naturalist, alas soon finds that he has been imposed upon, and that instead of eating the luscious slugs with which his soil abounds, the tortoise prefers his succulent lettuce and tender cabbage plants, not to mention his strawberries. The Water Tortoises, however, are with few exceptions carnivorous, and this must be borne in mind when making provision for the respective needs of the members of the two families *Testudinidae* (Land Tortoises), and *Emydidae* (Terrapins, or Marsh Tortoises). Generally speaking, it is the former which are favoured by the pet-keeper, and interesting creatures they are in captivity. They are usually on sale in summer, arriving here in vast numbers, though whether they go has long been a problem. In other countries than our own it is the custom to eat them and they are said to form very dainty morsels. It is astonishing the time these Land Tortoises will live in a state of captivity if they are not intelligently treated in the way of food. Nor are they the dull, stupid creatures that at first blush they would seem to be; on the contrary they soon become fairly tame and readily recognise the hands that feed them. The name Tortoise is a peculiarly appropriate one, having been bestowed on the group on account of their twisted legs.

LAND TORTOISES.

Varieties.—Those best suited to a life in captivity are natives of Europe, the most familiar species being *Testudo graeca*, *T. mauritanica*, and *T. marginata*, the first-named two having reference to their country of origin and the last and largest to the extended hind margin of its carapace. The Greek Tortoise may be differentiated from its two allies by its long tail having a claw-like end; while the Moorish Tortoise has like *T. marginata*, but a single plate in the tail vicinity and a plastron which is movable behind, as against the immovable plastron and double tail-plate of the Greek Tortoise.

Management.—If the Tortoises are to be kept in the garden they must be restricted by some means, or they will do a lot of damage. The position assigned them should be a sunny one and preferably bounded by a wall. It is then quite easy to rig up with boards, or a box from which an end has been removed, a comfortable retreat from bad weather, and especially if a framework on which some Willesden Canvas has been stretched well covers the retreat, thus protecting it from rain and scorching sun. Occasionally, one sees the Tortoise restricted by means of a coruscated

through a hole made in the hind margin of the shell. This will not appeal to the majority. Of course if the Tortoises can be allowed the liberty of a warm greenhouse and are fed properly they will not hibernate. Moreover, too, assuming that a pair have been kept (and this is better than keeping a single one), the probability is that eggs will be laid. In that case they should be placed in some moist sand on a frame generating a nice moist heat of 75 deg. to 85 deg. Fahr. In that case they should hatch out in two months or a little more.

In the event of one not having a suitable greenhouse in which the Tortoises, can be housed in winter, they should be allowed in autumn to bury themselves in the ground, marking the spot that they have selected. Or again they may be taken and placed in a box containing soil or leaves and stowed in a cool room until spring, when they will awake from their torpor and soon commence to feed, though not very readily at first.

Food.—The best food for Land Tortoises consists of lettuce, cabbage, grass, dandelion flowers and the flowers of buttercup; while it also exhibits a partiality for strawberries, currants, and many other garden plants.

MARSH TORTOISES.

These are very much flatter than their land congeners, and are, moreover, provided with webbed feet to suit the partial aquatic life that they lead. To keep them wholly in water, however, is cruel for they are also most capable walkers.

Emys Orbicularis (Syn. *E. testaria*), the European Pond Tortoise is the commonest species kept and is variable as to colour; there are two types, radiate and spotted in the former of which the colours radiate from the centre. Adult specimens measure from 5 inches upwards to 9 inches. To watch this Tortoise stalk its prey, whether fish or frog, is most interesting. In a state of nature they feed in the water, but when tame they will take food on land. These Pond Tortoises make a curious shrill noise at breeding time. The eggs are deposited on land, but the young are very difficult to rear. There is an American species—*E. blandingi*—black with yellowish spots, which is smaller than its European representative of the genus, that is said to become very tame, although we have had no experience of it; it prefers land to water and is a very distinctive Tortoise, with head black above and yellow beneath. *Clemmys leprosa* from Morocco has also been successfully kept here, but on account of its "fishy" odour cannot be recommended as a pet.

Food and Management.—As previously suggested these are in the main carnivorous, feeding upon worms, newts, fish, frogs, and various insects; while in captivity they may also be provided with raw meat, small birds and mammals. Generally speaking they do not exhibit the same intelligence as the Land Tortoises, seeming to avoid rather than to seek man. Where one can furnish these creatures with a small, sunny, duck-weed-covered pond, with a bank on which they can land to "sun" themselves, this should be an ideal spot. Such a pond, however, would need to be surrounded with wire-netting or the Tortoises would "stray." Provision should also be made of a suitable place in which they can deposit their eggs should they wish to do so: a nice light, sandy soil would be excellent. They should be allowed to hibernate in a box of moss and then be stored in a cool frost-proof place until the following season. If one can give them plenty of suitable food, and a warm greenhouse having a pond in which the water can be kept chilled, or one of the vivariums making provision for this latter, these Marsh Tortoises will not hibernate.

PEARS'
READY
RECKONER.

Pears' Ready Reckoner

From One-sixteenth of a Penny to
Twenty-one Shillings

In the following tables any number of articles, separate weights or measures, days, weeks, months or years—from 1 to 5,000—are reckoned, at amounts from a sixteenth of one penny to one guinea, in individual sets, each table being complete in itself. Up to 20 each number is worked through progressively in the shorter tables on this page; then follows 25—as a quarter of a hundred, and every multiple of ten next in order, with 52—as the number standing for the weeks in a year, interpolated in its proper place.

In the longer tables—from the next page to the end—every number from 1 to 100 is reckoned out. Beyond the number 100, the figures standing for multiples of dozens up to the gross (144) have a line each, as has also 112, the number of pound. in a cwt.; with an entry for 365, the number of days in the year, breaking the even hundred progression; and one at 2,240—for the purpose of showing at a glance what the cost per ton comes to of anything priced at the amount per pound shown by the table—inserted between the 2,000 and 3,000.

The reckoning for every possible combination of whole numbers can thus be readily arrived at where not expressly given, by adding together the items indicating the values attached to composing numbers. Thus 3,336 articles at one-twelfth of a penny each would come to the total of 3,000+300+60+6, or, as will be seen, £1 os. 10d.+2s. 1d.+5d.+0½d., an aggregate equalling £1 3s. 4½d.

THE SCIENCE OF SOAP

AN EXTRACT FROM A LECTURE ON HEALTH.

By ANDREW WILSON,
Ph.D., M.B., F.R.S.E., F.L.S.

*Lecturer on Physiology and Health to the George Combe Trust and
Gilchrist Trust Lecturer. Author of "A Manual of Health Science,"
"The Modern Physician," &c.*

Dr. ANDREW WILSON is acknowledged to be a leading authority on the Science of Health. Not only has he studied the science deeply, but he has an almost unequalled knowledge of the subject in its manifold practical bearings, as his numerous lectures and writings effectively testify. Therefore, anything that he may have to say on so important a theme as Soap cannot fail to be worth reading.

"The Great Civiliser." Soap has been termed "The Great Civiliser." In respect of the fact that its use implies freedom from dirt, it might with equal justice be termed the harbinger of Health, seeing that cleanliness sums up in a single word the essential condition which underlies all hygienic practice.

"Cleanliness" of body, of garments, of surroundings, of houses, of drains, of food, of air and of water, represents the aim and end of all health-teaching. In

proportion as we attain and maintain cleanliness universally and abolish dirt, we prevent disease, save life, and promote the happiness of mankind. Clearly soap, as a means of Sanitary grace, is not to be lightly esteemed.

It is the foe of the microbe and the enemy of disease, and the Soapmaker's labours may therefore, in a very real sense, be said to run in parallel lines to those of the sanitarian's work and of the doctor's practice.

The Personal Side of Cleanliness. Leaving the purely domestic and disinfectant uses of soap out of sight, the personal side of the cleanliness question may be said to offer a very interesting study in connection not merely with the preservation of health, but also in respect of the promotion of what one may term the æsthetic side of life. Health implies beauty and cleanliness is the foundation of both. While the care of the skin naturally falls to be considered as an all-important element in health-culture, such care, implying the wise selection of a soap, must naturally include the making of most of what personal attractions we possess. For the relation of skin-health to soap is much closer than is usually supposed.

Soaps to be Avoided. Crude soaps, coarse soaps, or those impregnated with deleterious colouring matters, are too often the cause of skin-troubles often of an intractable kind. Then, we have to distinguish between medicinal soaps intended for the cure of skin-troubles, and those intended for toilet use: a distinction, this, of great importance. Soft soap is an excellent cleanser of woodwork and other things; it would ruin any skin to which it was applied. Medicated soaps are useful in the hands of the physician; the healthy skin requires no drugs applied to it, any more than the healthy stomach demands the continuous administration of drugs. Thus we see there are soaps to be avoided for personal use in health, just as there are others suitable for daily employment by way of promoting the welfare of the skin.

The Relationship of Soap to the Skin. It behoves us, in order fully to comprehend the relationship of soap to the skin, to consider briefly what the skin itself is. No knowledge of any bodily function can be complete or satisfactory which is not founded on an appreciation of the nature of the organ or part with which we are dealing. Popularly regarded, the skin with many people stands simply for a body-covering. It is very much more. It is in truth a somewhat complicated structure or tissue.

It consists of two chief layers, the outer skin, "Scar" skin or "Epidermis," as it is named, and the under skin or "Dermis." There are other layers included in the skin texture, but it will suffice for the present purpose to recognise these two main divisions. Most of us know the difference between the two layers.

Practically, in shaving, a man makes a clear distinction between them. If he keeps to the outer skin all is well; if, however, he allows his razor to descend to the under layer, he soon becomes aware of one difference at least, if not two, between the skin-tissues. For when he cuts himself he draws blood and he feels pain, proving thus that, while the upper skin is destitute of blood-vessels and nerves, the under skin possesses both. We discover on close examination that the outer skin is in fact a production of the more vital under layer. It is composed of microscopic cells which are produced practically on the upper surface of the under skin.

Skin-Renovation. These cells do not survive long. There is a perpetual procession of them passing upwards in layers, getting drier and more scale-like as they ascend, until they arrive at the surface of the outer skin itself. There, as mere dried scales, they are worn off by the friction of our clothes and by washing, their places being taken by other cells produced and pushed upwards in the same manner as were the lost cells.

We might compare this shedding of the outer skin cells to a process of "Moulting." The lower animals exhibit this feature at intervals or periodically; man is always moulting.

If such be the nature of the outer skin, that of the under skin or "dermis" is of a very different kind. The under layer is an organised structure, that is to say, it consists of living cells and is well supplied with blood-vessels, while the ends of the nerve-fibres, through which we exercise the sense of touch, end in little projections of the under skin-layer. When we touch anything, we therefore feel it by the nerve-ends in the under skin, through the upper skin.

The Function of the Skin. The blood supply of the skin is very extensive. So fine are its blood-vessels that even the point of a needle must wound a large number of them. This distribution of blood to the skin leads to another and most important consideration, namely, that which teaches us that part of the skin's duty is to serve as an organ for getting rid of so much of our bodily waste which is the result of our bodily work. In fact, one might well compare the skin to a lung spread all over the body's surface. Physiologists will tell us that the lungs, skin, and kidneys form really a trio of organs performing similar work only in different ways, that work being "excretion," or, as it has already been termed, the getting rid of waste. Very much the same substances, but in different proportions, are excreted from the blood by all three, and it may be said in addition that the skin has a power of absorbing oxygen gas, so that in this respect it shows an approach to the lungs in the nature of its duties.

Miles of Sweat Glands. How the skin acts as a channel for the exit of waste is revealed to us when we discover in the deep layer numerous "sweat glands." Each is a coiled-up tube, the end of which passes upwards to open on the skin-surface in a "pore." Around the glands are dense networks of blood-vessels, and it is easy to conceive how the waste matters can strain through their thin walls and so reaching the sweat-tubes be passed upwards to be discharged on the skin-surface as perspiration. Any interference of a serious kind with the skin-function, just noted results in disease or death. It would be quite possible to "suffocate" an individual by gliding his skin over with an impermeable layer, and this result actually happened in one case in which a child's body was covered with goldleaf, that he might take part in a procession at Rome. It is in the palm of the hand and sole of the foot that sweat glands are most numerous. Each little sweat-tube if uncoiled would measure about one-fourth of an inch, and the late Sir Erasmus Wilson calculated that in a single square inch of the palm, about 731 feet of sweat-tubing is contained. Similarly it has been calculated that in the whole body there exists 20 miles length of such tubes.

There are other glands in the skin called "sebaceous" glands. These supply a fatty matter, the use of which is to keep the skin supple. These glands are found also opening into the sheaths or hairs, and it may be supposed the matter they secrete represents a kind of natural pomade. When the tubes of these latter glands become blocked up with the fatty secretion, and the top of the little plug of fatty matter becomes coated with dust, we get what are called "blackheads" in the skin.

Soap and the Body's Health. All this information has an important bearing on the maintenance of the matter of skin and body alike, and incidentally, on the use of Soap. For the body's health depends to a large extent on the proper discharge of the skin's duties, just as the skin, in turn, sympathises very strongly with different bodily states. The skin is a regulator of the temperature of the body, through the blood, which is ever circulating through it. The production of perspiration and its evaporation implies loss of heat, hence the rapid cooling of the body after copiously perspiring. In cold weather less sweat is produced, the loss of heat is diminished, and the bodily heat is then conserved. These facts enable us to understand what chill implies, with its effects propagated by the nervous system to the lungs or other parts.

The necessity for strict cleanliness in the matter of the skin and for the use of a pure soap becomes clear when we consider the functions of the skin-glands and their constant work in pouring out on the skin-surface so much of our bodily waste. Yet another fact must be borne in mind, namely, that the old skin-cells, which are always being shed, demand equally the acts of washing for their removal, and for this reason also it

may be said, there arises the necessity for frequent change of our undergarments. The exercise of cleanliness all round is therefore more than justified by all we can learn concerning the duty of maintaining the healthy action of the skin, and equally by what we know of the waste products our bodily covering gives forth.

The Absolute Necessity of Soap Purity.

A soap fit to use and such as can exercise no injurious effects on the skin must first of all be of pure quality. It must contain no deleterious ingredients and no objectionable or irritating colouring matter. To please the eye counts for nothing in the matter of soap; the great essential is purity. Next in order comes the matter of economy. Soaps loaded with water represent so much money wasted, whereas a soap in which the quantity of water has been reduced to the minimum must prove economical, because lasting. Crude soaps naturally irritate the skin, and in place of removing the skin-debris literally rasp off the cell-layers which are not yet ready for removal. Hence many cases of tender skins are to be attributed to the use of improper soaps, which as an authority puts it "should only be used for washing floors."

THE SOAP THAT IS ALL PURE SOAP. Many years ago, following the lead of Sir Erasmus Wilson, the late Mr. Startin, the famous skin specialist, Professor Redwood and others, I bore testimony to the purity and excellence of a soap, the name of which has become a suitable household word. I allude to PEAR'S SOAP. For years the excellence of this soap in respect of its unvarying purity has been fully maintained. It owes its fame and reputation to its unchanging character, and to its non-irritating nature, and it is this latter feature which has made it a special favourite for nursery use. The delicate skin of the infant requires a soap of bland character, and PEAR'S SOAP fully justifies the confidence, which mothers and nurses repose in it. Again, it is an excellent detergent and removes dirt particles very easily, while from the point of view of economy, PEAR'S SOAP, as it has been well declared, is all soap and can be used till it has become of the thinness of a sixpence.

THE SOAP FOR THE COMPLEXION. Attention to the complexion is a matter which concerns everyone, and the value of a pure non-irritating soap in preventing the development of blotches is therefore to be regarded as a *sine qua non* for those who desire to maintain a fair skin. PEAR'S SOAP is a necessary to the toilet of the fair, while it is equally adapted to the use of the sterner sex, and makes for shaving an excellent lather, not apt to irritate the skin as do many shaving soaps which contain potash. On these grounds PEAR'S SOAP should continue to enjoy the confidence of the public, for no purer article of its kind has ever been offered to the people.

THE SKIN AND COMPLEXION

WITH SPECIAL REFERENCE TO DIET, CLOTHING,
BATHING, AND COSMETICS.

By JAMES STARTIN

Senior Surgeon and Lecturer to the London Skin Hospital.

The charms of a clear, healthy skin, and its usual accompaniment, a fine complexion, are universally acknowledged. It forms one of the chief elements of beauty, and those who are endowed with these beneficent gifts are indeed favoured; but if they wish to retain this beauty, they should give it their especial care.

From the earliest period to the present time never was there an era when women did not try to make themselves beautiful.

The Care of the Complexion. The care of the complexion is a duty which every woman owes to herself and all parents to their children. Regularity of features and a perfect development of form are of little avail if the complexion is not good.

In fact, the complexion is the chief charm of beauty in our own race, for what finer complexions in the world do we see than those of our own countrywomen?

Many people grow careless of their appearance after a certain time of life; no doubt the cares and troubles and worry in the race for life have something to do with this. We should be, therefore, careful to bear our cares and troubles with a healthy mind, and if we wish to preserve the beauty of our complexion, should take far more care in our modes of life and daily food.

More than 2,000 years ago Xenophon wrote, "Men regarded a genuine complexion as most pleasing."

The Health of the Skin. The conditions of life in which we live, as a highly civilised nation, exert a powerful influence upon the structures which combine to make up our organism, but perhaps their influence is most plainly seen upon the skin. A proper care, therefore, of the skin is an important factor in the prevention of most cutaneous disorders. The health of the skin is much the same as the health of our bodies. We may define health, if we can, but it is indefinable.

It is that state of our bodies in which the functions go on without our notice or observation, and in which existence is felt to be a pleasure; in which it is a kind of joy to see, to touch, and to live. This is health. Yet the skin is apt to be looked upon and attended to by the majority of the community less than any organ of the body. It should not only be considered as a mere covering to defend us from the effects of heat or cold, but as one of the most important organs of our body, without the constant activity and agency of which we must look for neither health nor long life, and the neglect of which in modern times lies the secret source of numberless diseases and evils that tend to shorten our existence. And from whatever cause they result, the morbid phenomena of eruptions of the skin show themselves at all periods of life, in every rank, and in all conditions of civilisation. But it is the working classes of the community who are mostly exposed to

their influence, and consequently it is mostly amongst the poor that the greater number of these diseases are found.

Dust and Dirt. The artisan in his several trades finds a natural source of skin disease in the dust and dirt in which he labours, often very irritating, and from which he cannot, or can very imperfectly, protect himself, unless he gives up that employment which furnishes his daily bread. Not only the artisan, but drapers, grocers, dyers, bakers, skin-dressers, and other traders find that their assistants occasionally suffer by absorbing the dust from their trade into the skin.

Disorders of the Skin. The skin is the greatest medium for purifying our bodies, and every moment of our lives a multitude of useless, corrupted, and worn-out particles evaporate through its numerous small ducts in an insensible manner. This evaporation is inseparably connected with our lives and the circulation of our blood, and by it the greater part of all the impurities of our bodies are removed. If, therefore, it be inactive and its pores be stopped up, an acidity and corruption of the juices will be the inevitable consequence, and most dangerous diseases may ensue. A very common public error is that all disorders of the skin are contagious. Quite commonly servants and workpeople turn aside and avoid any one in the same service if affected in this way.

The Question of Contagion. Numbers of poor girls are thus driven into any asylum to which they can gain admission, and the Union is the only place of refuge from a prejudice most undeserved and unwarrantable. Men-servants also suffer too often by this uncalled-for avoidance. The vicinity or even the bare mention of skin diseases seems to unsettle the equanimity of some people—especially nervous, weak-minded individuals. But let me reassure them; for few eruptions of the skin are really contagious, and even those that are, are hardly ever seen by the public in an actual condition of contagiousness.

If any further inducement were needed to urge us to take consideration of so important a subject as the care of the skin, it might be found in the risks attending an invasion of that terrible and devastating disease, Asiatic cholera. Nothing that we can do is so likely

to preserve us from that dire disease—and indeed, from every disease of an epidemic or contagious kind—as a proper and judicious care of the skin.

Sanitary Precautions. The instructions laid down by our Sanitary Boards for securing our country against cholera are happily so good, and they contain recommendations having reference to the maintenance of the skin in a state of cleanliness, warmth, and health; and it is only by a knowledge of the nature and functions of the skin that we can safely hope to succeed completely in effecting this object. Fortunately, if there is one characteristic which distinguishes an Englishman or woman, it is the almost universal habit of cleanliness—the “love of the tub.” Of this I purpose speaking later on.

Skin Eruptions. It would appear that, at first sight, skin eruptions in ancient times were either more frequent, or that the disgust with which they were regarded had a greater influence on the community at large than is at present the case. At the period of the establishment of our royal hospitals (St. Bartholomew, Bethlem, and Bridewell), the leper, as the unfortunate individual was called who was afflicted with a skin eruption, had a place allotted to himself, “to keep a little of the evil.” He was in a manner confined to a district, beyond the bounds of which he dared not venture under the penalty of death; indeed, so severe was the law in such cases (leprosy having been held one of the five plagues under the Sanitary Code in most European countries, and I believe in our own), that anyone convicted of having had communication with a leper rendered his life a forfeit to the State. Common sense in modern times, however, has long since exploded the belief that the affection called leprosy is contagious in temperate climates. After the Crusades every disease of the skin became an object of suspicion, without discrimination or even a cursory inquiry into its nature. Under the general denomination of lepers thousands of helpless wretches, whose only crime was poverty, were condemned to noisome imprisonment and banishment from all ties of friendship and kinship. At that time the number of leproses in Europe amounted to 21,000, and we read that in Paris, in the façade in such a building, a gibbet was erected for such as dared either to enter or escape without permission.

Leprosy. It may be interesting to state that the site of St. James's Palace was anciently occupied by one of these leper-houses, and that the park adjacent formed part of the domain from which it derived its support, until Henry the Eighth, in his kingly wisdom, converted this ancient charity into the palace, as it still continues. Such was the charitable care of the suffering community in ancient times. But it is only within the last few years that special notice has been taken of these diseases by medical men, and special hospitals and special departments in hospitals established for their alleviation.

Character of the Skin. The soft yielding texture or integument forming the external covering of our bodies, well known by common designation as the skin, though apparently one membrane of evidently complex structure, in reality consists throughout its whole extent of three layers, which, besides performing the important office of protecting the parts beneath from injury, constitute at the same time the seat of the sense of touch and the organ of sensible and insensible perspiration; and we are here reminded of the expressive lines of Pope—

“In human works, though labour'd on with pain,
A thousand movements scarce one purpose gain;
In God's, one single aim can sit and produce,
Yet serves to second, too, some other use.”

The apparatus for cutaneous absorption, imbibition, as it is called more properly, the three layers, furnish also a locality for innumerable glands or bulbs, producing hair, and everywhere covering the body, adding so much to its softness and grace; a class of little cavities, which secrete the unctuous matters to lubricate the skin, called the sebaceous glands, and, finally, for the sudariparous or perspiratory glands.

Functions of the Skin. Yet, with so great a variety of offices and parts, the extent and services of this interesting membrane are not confined to the outer

surface only, for the skin is found to be continued inwards at all the openings of the body, and to become the mucous membrane of the mouth, nose, throat, lungs, stomach, and other organs; so that the cutaneous surface may be said, like a circle, to have neither beginning nor end, but forms one beautiful investing membrane for the whole body, inside and out, which so admirably accommodates its services to the various parts that perhaps no structure could be imagined more illustrative of Divine arrangement, by combining unity of purpose and design with diversity of functional offices, and so gracefully adapting itself to the different and varied movements of the body, without wrinkle or inequality, as to have furnished Burke, in his essay on the “Sublime and Beautiful,” with one of his happiest illustrations.

Sensitiveness of the Skin. Though the skin is so surprisingly yielding and delicate, it is well constituted to resist external agencies, which property is marvellously increased by education or habit; to the horny palm of the smith, for example, the dewdrop and the red-hot metal prove nearly innocuous in their action.

Yet so wonderfully sensitive is the organ of touch in the skin that in the blind, deaf, and dumb, it has furnished a medium of communication which in minuteness of perception has nearly rivalled, while it affords a substitute for, the lost senses.

Whilst thus the skin may be said to connect each of us with the external world, it affords at the same time the safeguard and protection of the parts within, offering, according to their several necessities, great density of texture for a shield or defence, as before instanced in the hands and feet, or a delicate and wonderful tenacity, as on the lips and other organs, where exquisiteness of sensation constitutes the prominent function to be developed.

The Fingers. The ends of the fingers may here perhaps present themselves as seeming exceptions to this statement, but when we speak of the anatomical arrangements of the skin we shall at once perceive increased cause for admiration of these facts, and wonder at the contrivance for admitting free exercise of the sense of touch in parts so thickly covered by cuticle.

Of the three layers or divisions of the skin the *first*, or outermost, that which meets the eye—the *scarf-skin*, or epidermis; the *second*, in which the coloring matter of the different human races is deposited, is called the *rete-mucosum*, or *malpighi* (after its discoverer, Malpighi); and the *third* is called the *true skin*, the *cutis vera*, *dermis*, or *chorion*.

The Cuticle. The cuticle, when separated by a blister or other means from the living body, is found in all races of men, blacks as well as whites, to be a diaphanous, elastic, white or greyish-white membrane, rather darker, however, in the negro races, and, from the grooves intersecting it, apparently reticulated, the outer surface being somewhat convex and polished from the oily matter thrown out upon it by the sebaceous glands or follicles, the inner surface concave, rough, and irregular, an appearance which, if regarded with slight magnifying power, is found to arise from numerous small points or processes like the pile of coarse velvet; these are the hollow, tube-like continuations of the cuticle dipping into the pores and inequalities of the rete-mucosum, the second membrane of the skin, and into the true skin or dermis. The third membrane, as it were, forms the medium of communication between all those parts and channels through which the hair, and sebaceous and sweat-ducts pass, each of these minute tubes or processes being like an inverted finger or a glove, the duct, hair, etc., perforating its apex something after that manner.

A Protecting Membrane. By a beautiful provision of nature the cuticle may be said to be sort of varnish, perfectly insensible, which protects the more delicate parts of the skin and the organ of touch from injury.

Were our bodies without this covering, not only might any noxious weed we crush in our progress produce lethal effects, but we could scarcely perform the common offices of life without risk. In our profession this protecting membrane daily and hourly asserts its preservative influence; with this safeguard

we can handle with impunity but only deadly poisons, but sources of contagion themselves.

Thus we see the advantage, nay the necessity, to our well-being of bearing about with us an inanimate exterior, and can admire the wonderful wisdom of the Creator in this external adaptation of our bodies to the world without.

We now come to the question, What is the soundest state or condition of the skin, or that which most contributes to it and thus its arm indicating a high state of health. It does not depend upon whether the person is of sanguine or bilious temperament, of ruddy or sallow complexion, but whether the skin exercises its functions in a proper manner. I will now endeavour to show you how it may.

The Management of the Skin. The conditions, therefore, necessary to maintain the skin in a sound and healthy state, to restore it when disordered, to second our efforts when engaged in treating some of the many eruptions to which it is liable, may be classed under three heads—

1. That the body should be, if possible, well and judiciously nourished.

2. That no undue tax or strain should be put upon the skin.

3. That the skin be put under proper rules of management as to general hygienic surroundings, diet, clothing and exercise. The more exercise we take in the open air the better for our complexions; we do not take half enough, lie especially.

Diet and Skin Health. Now with regard to diet I should like to say a few words, as the health of the skin is much influenced thereby.

In the first place, our food is in a double manner a source of warmth, by supplying the material requisite to balance the continual waste going on in the body, and, secondly, by conveying into the system those elements which by their chemical composition engender heat; and to ensure these results our food must be wholesome and sufficient, and must combine all the varieties, animal and vegetable, which are bestowed upon us, viz., the aqueous, the albuminous, the saccharine, and the oleaginous. The first is necessary, and enters largely into the component parts of our body; the second, from our animal food; the third, from the vegetable; and the fourth, from both the latter. Let me give you a good maxim: *Happy is the man who only eats when he is hungry, and drinks when he is thirsty.*

Periods of Taking Food. The periods of taking food usually adopted in our country, in accordance with convenience and recurrence of hunger, are those which are best suited for the purpose of health, viz., the morning meal, the mid-day meal, and the evening meal.

The morning meal, or breakfast, should be taken between 8 and 9; the mid-day meal, the dinner of our forefathers, the second breakfast of the French, the lunch of fashionable life, is generally, and should be, taken between 1 and 2 o'clock; and the evening meal, the supper of our forefathers, the dinner of the present day in fashionable society between 7 and 8 o'clock.

Among the ancient Greeks the three meals of the day were called the "ariston," the first, or morning meal, taken at sunrise; the "deipnon," the chief meal, dinner; and the "dorpon," the evening or sunist meal, supper.

The Athenians took meals as the French, and they called them "ariston" and "deipnon," excluding the "dorpon," and sometimes the "ariston" was regarded as luncheon, the prandium of the Romans.

Quantity of Food. As regards the quantity of food to be taken at all times, no doubt it is best to err on the side of moderation, and I have no hesitation in recommending too great a variety at a single meal, however much variation of diet may be useful. A variety of dishes is simply an injurious device for overloading the stomach. Before I commence referring to special articles of food, let me urge upon you the great importance of regularity of meals and sufficient time to eat them. Upon this rule depends to a great extent our health. Irregularity in this respect, produces, as you know, indigestion, flushing of the skin, and one of the most disfiguring eruptions, and that on

the face. It is not all red faces and red noses that proceed from strong drink, though many do.

The diet for anyone who suffers from an eruption should be fairly good; above all, the day should be commenced with a substantial breakfast of light food, but not with hot roast meat, as is the custom with some persons; the stomach is not able then to digest it. Fish, boiled bacon, eggs occasionally, cocoa or cocoatina, coffee for some, tea for some, for few persons are able to digest the same things—some coffee, some tea. Some take porridge, but my experience shows me it cannot be taken regularly south of the Tweed. It is much too heating in the south of England; indeed, I have seen eruptions caused by eating it, especially among children.

Beverages. Now milk is a mixture of the four staminal principles of food that I have mentioned before; in it, therefore, we expect to find a model of what an alimentary substance ought to be. Some cannot digest milk; then I recommend them to take soda-water with it. It forms a very suitable portion of our daily food, therefore.

Coffee. Coffee, if properly made, is a wholesome beverage, but it requires making. It, the berry, of two or three kinds, should be freshly roasted and ground, and thoroughly boiling water passed through it before it is required. Those of you who know this must know how vastly different it is to the stuff called coffee, as it is bought, and often mixed with that wretched drug chicory.

Tea. If tea be preferred, it should be made with some variety of pure black Ceylon, India, or China tea, not green. A correct infusion is made by pouring boiling water upon the tea and allowing it to stand from two to five minutes at the most. Let me urge you to try these methods, and I vouch you will not be disappointed.

Solids. For solids, variety is best—not eggs and bacon, bacon and eggs every morning, or eggs alone, as they are too luscious to take regularly. I take fish (not kippered fish) one morning, boiled bacon another, it is almost as good as cod-liver oil to weak persons.

Meat Eating. The rule is, therefore, our food should be fair in quantity and good in quality, but light. A fair amount of meat should be taken, but never in excess. The people of England are accustomed to eat far too much beef and mutton without variation, which only stimulates the skin to gross and unhealthy action and appearance. Servants, where so much meat is consumed in well-to-do families, make good patients to the doctors. All rich and heating foods taken in excess, such as roast pork, salt beef, veal, jugged hare, many soups, badly cooked pastry, shell-fish, new cheese, raw vegetables, dried fruits, sweetmeats, should be studiously avoided by those who have any tendency to eruptions; but even in health the skin often becomes red and irritable after such things.

Vegetable Diet. We should take a more mixed and vegetable diet; and let me tell you, ladies, that vegetarians, possess the finest complexions of any people in the world; not that I advocate vegetarian diet in itself alone. The tendency, as I said before, is to take too much red meat, and too often. We should take much more vegetable diet than we do, and more fish—that essential nerve and brain-nourishing food—some unadulterated bread, whole-meal bread and brown bread, once-cooked meat, potatoes well cooked, all sorts of green vegetables, marrow, celery, tomatoes, leeks, and others so little known, rice, farinaceous food, beans, peas, light puddings of all kinds.

All this has been most ably brought forward in the lectures on cooking at the last most successful International Health Exhibition. No person can expect to have a nice complexion who eats meat, beef, and mutton, day by day without variation.

Alcohol, Injurious. My attention has been lately much drawn to the fact that in my practice so many disfigurements of the skin are entirely due to drinking intoxicating drinks to excess, and amongst the upper ranks of society too; and, further, it is a painful fact to relate that there are 50,000 prisoners in our jails. Sixty per cent. of the inmates of our lunatic asylums are victims to its direful influence; and there are 1,000,000 paupers in our workhouses and elsewhere, and

plenty ready to follow them, only through excess in drink. I find more than 60 per cent. of the dreadful cases of eruption in my hospital are either brought about by its influence, or those eruptions that are either inherited or acquired are materially influenced to the bad by its abuse.

Spirits and Ale. Instead of the vile concoctions called spirits, and that wretched stuff which is sold as ale to our working classes scarcely ever unadulterated, if we could prevail upon them to take less intoxicating drinks, how much less we doctors should have to do. This advice applies to the upper as well as the lower ranks of society. A young American medical man, who had just come from the medical schools of Germany, visiting the practice of my hospital, told me that in the whole course of his three years' study and residence in Germany he never saw a drunken man or woman in the streets, or a woman enter a public house. I am sorry to say we cannot say this.

Sir Andrew Clark says: "Is it possible that the teaching of science or the dignity of our profession, any more than the calls of patriotism, humanity, love to our neighbour, morality, and religion, can prove that we are wrong when we advise those that come in contact with us, as patients or in other capacities, to abstain from the poisonous and pernicious use of alcoholic drinks?"

The Joy of Health. I venture to say to you that there is a certain joy of existence—a sense in which one feels what a pleasure it is to look, for instance, upon green fields and happy birds, to hear pleasant sounds, to touch pleasant hands, to know that life is a satisfaction. *This is a state which, in my opinion, is always injured in some way or other by excess in alcoholic drinking.* This is a state in which, sooner or later, the music goes out of tune, as regards its influence upon the health of our skin. Perfectly good health will, in my opinion, always be injured by alcohol—injured in the sense of its perfection and loveliness. The complexion soon loses its bloom and the countenance its cheerfulness.

Complexion and Cosmetics. A healthy and clear skin is the chief object of every untutored woman, and a point in connection with its care demands remark. It is the employment of cosmetics or powders for the complexion; are they harmful or not? This, in my opinion, depends entirely upon the nature of the applications employed. *Many of the lotions and drings used and advertised for the skin contain harmful and positively injurious substances, and I have seen numbers of instances where acne and other diseases have been caused by them.*

Cosmetics may be defined as substances which are intended for application to the skin with a view to improving its appearance. However they may be prepared, whether as washes, powders, or pastes, they carry out their objects in some of the following ways. By concealing the eruptions of the skin, or some cutaneous affection, or hiding a coarse skin or some local injury or scar; and frequently they are used, not with the object of hiding any blemish at all, but merely to add an artificial colour to the complexion or a whiteness to the neck, arms, or hands.

The best cosmetic is an absolutely pure toilet soap like Pears', which induces the natural conditions necessary to a healthy refined complexion.

Blooms. The Romans and Greeks appear to have been accredited with the power to enhance their personal charms with many and various "blooms" and cosmetics, and many years ago a list was published of the various perfumes that they used on such occasions: mint for the arms, palm-oil for the cheeks and breast, marjoram for the eyebrows and hair, and ground ivy for the neck. History relates that the French then became the most renowned perfumers in the world, inasmuch as it is related that Diana of Poltierre preserved her complexion to a good old age; and Anne of Austria, too, introduced a wonderful cream, which was used to whiten the hands and shoulders. In England we are mainly indebted to the patronage of Queen Elizabeth for the introduction of cosmetics.

Powders. There are some skins which are tender and fine, and which may be prevented from becoming rough and broken by the occasional dusting on of some

simple powder, such as starch powder, French chalk, or talc, with the addition of a little salamine powder or boracic acid. *But I should emphatically condemn all powders which contain preparations of mercury, arsenic or lead, so often used by fashionable ladies of the present day.* And such powders, as used to impart a bloom to the face (on which much galeaty, hot rooms, late hours, ices, stimulants, or sedatives show their mark), are undoubtedly injurious.

The skin is a beautiful but delicate membrane. It is easily injured by many causes, acting from within and without, and requires to be carefully guarded against many injurious influences. *With a little knowledge and a little trouble the existing beauty of the skin may be made more enduring, and the natural defects so far subdued and ameliorated that practically they cease to exist.*

Black Spots. Perhaps some of the commonest of the minor disfigurements of the skin are the small black spots which appear on the surface. These are accompanied with redness and flushings. They are seated below the scarf-skin, and in the surface of the true skin, and are due to congestion of the sebaceous follicles. The pallid or sallow complexion, so often seen, is similarly caused by a weak and insufficient action of the small vessels of the pores. All who take much interest in the preservation of the skin should consider that its health and beauty mainly depend upon the cleanliness and free action of these transpiratory pores. If these become choked up, and charged with foreign matter, it is obvious that the regular functions of the skin cannot be fulfilled, and the result must, sooner or later, show itself in an accumulation of black specks or deposits in the mouths of the glands in the skin.

It is important, therefore, in all derangements of the skin, to give no time in the application of suitable remedial treatment, as certain morbid conditions thus produced soon lead to the formation of coarseness and wrinkles, and when once produced are difficult to remove.

Wrinkles. Wrinkles, of all the enemies of a good appearance, are viewed with the greatest apprehension, and they are caused by a diminution of the fatty particles of which the skin is partly composed, especially under the eyes and at the corners of the mouth.

When this subcutaneous fat diminishes, the skin begins to fall into lines, and loses its smooth and even surface. No time should be lost in counteracting this alarming tendency, by the application of certain astringent preparations, or by massage or rubbing the wrinkle and the adjoining skin. This should be practised daily for a short time, and after a while much may be done to restore the smooth surface of the skin and a more youthful appearance.

Freckles. Freckles, though not so important to the appearance of the complexion as wrinkles, are very detrimental to good appearance. They are, as we mostly know, caused by exposure to the sun and wind, and are not constitutional or permanent when carefully treated.

We then have the pale, clammy, and greasy skin. This is a very unpleasant and inconvenient defect. It is due to an abnormal distension of the sebaceous and sudoriferous glands of the skin. The disfigurement may also be relieved by suitable treatment.

Free Transpiration. All clothing should be such as shall permit free transpiration from the skin, and, moreover, convey the transpired fluids from the surface; otherwise cold, irritation of the skin, and other bad consequences follow. And everyone is practically aware that a loose dress is much warmer than one which fits tightly. The explanation is obvious: the loose dress encloses a thin stratum of air, which the tight dress is incapable of doing. The maxim, therefore, is that we should *never wear our clothes too tight.* I notice many ladies in the present day and present fashion do so; but they will find what I say true when the really cold weather comes. They not only face themselves in too tightly, but wear too tight and too pointed-toe boots and shoes. If they only knew how serious a matter it is—destroying their lives and displacing all their internal organs, causing pale, sallow complexions, and the pointed-toe shoe

utterly destroying the shape of the foot in a few years. Suppose women, when they have got a husband, do not mind this, but the husbands do.

Woolens. Those whose skins are able to bear it find wool, or flannel, is the best material to wear next the skin (never red flannel, and I will tell you why presently), by reason of its absorbing and heat-retaining properties; to those who cannot, then fine linen is best. For the outer clothing woollen stuffs are by far the best, preserving the heat longer than other materials. There is scarcely any organ of the body that may not be affected by undue or irregular action excited in some portion of the surface circulation of the skin; how necessary, therefore, it is for our health's sake, as well as our skin, that we should be most careful what we put on. *I notice also that veils are far too much worn by women of the present day. They often conceal but do not preserve a good complexion.*

Baths and Bathing. If there is one thing we English pride ourselves upon more than another, it is upon the fact that we do more bathing than any other nation in the wide world. Judge for yourselves, those of you who travel. The limited quart of water is often a cause of no mild complaint.

But to the casual eye the subject is a pardonable one, that of looking at the fact with pride, but if we examine the position more carefully, we shall find our self-satisfaction is a little premature.

In these days, when the arts and sciences in their daily advance multiply the comforts and resources

and in truth be a cause of wonder if so essential a means of prolonging and maintaining the vigour of life should have been neglected as is presented by efficient public bathing establishments, where the fatigued workmen (for we are all workmen, or should be, to keep well) may gratuitously, or for a small sum, relieve himself of the vicissitudes of his labour. At the present time more attention, I am glad to say, is being paid to the subject in London and several large towns; but there is much room for improvement.

Public Baths. Public baths are being slowly established here and there; and it may fairly be calculated that these baths so built will end in restoring those sources of healthy enjoyment so well resorted to by our ancestors, for it may be observed that the origin and use of baths and bathing may be traced to the most remote antiquity, and were probably suggested to the ancient inhabitants of the world by the various mineral and thermal springs which are found in most countries. Thus we are told by Diodorus, who wrote on the subject 300 years ago, that every ancient nation of whom we have records, employed baths as one of the most powerful agents in the preservation of health and the removal of disease, and indeed with reason, for experience has failed to supply a remedy of greater efficacy on the human economy than a judicious administration of heat and cold.

Baths of the Ancients. If we look back to the days of fable and allegory, we find it affirmed that the first baths were consecrated to Hercules, and that Minerva prepared a vapour bath to refresh this hero after his extraordinary labours. Homer sung the praises of the bath in his *Odyssey*, as is testified by Pope. Hippocrates, the father of medicine, has also not failed to add admiration to establishments that were then becoming more common and useful. Plutarch and Josephus have left descriptions of the baths which adorned the towns in which they dwelt. From the testimony of Pliny we learn that the first public baths of the Romans were constructed in the year 444 by Apicius Claudius. These baths have preserved a character of simplicity and sobriety in perfect harmony with the manners of the day. The historian Justin mentions the fact of the importation of baths into Germany, Gaul, and Britain, and verifies the establishments in the vicinity of Roman remains scattered over this country vouch for the accuracy of his statement, whilst, spectre-like, they furnish silent reproof of the modern neglect of a sanitary practice to which our ancestors attached so much importance.

The Augustan Baths. The Romans in the time of the Emperor Augustus according to the reports of Vitruvius, attached gymnasia, or places appropriated to public games, to their

baths, and later the Emperors Nero, Vespasian, and Titus gave these edifices so much magnificence that it was observed they were more calculated to convey the glory of their founders to posterity than to prove of public utility. Indeed, to so great an extent had luxury and licentiousness usurped the natural and salutary purposes of public baths in the Roman Empire, particularly in Rome itself, that the early Fathers of the Church anathematised their use in the strongest terms, both in their discourses and in the Council of Laodicea, yet without subverting their abuses, which perhaps contributed in no small degree to the overthrow of that queen among nations, by the luxury, licentiousness, and effeminacy which they engendered.

Roman Baths. It is sincerely to be hoped that such a state of things may never again disgrace institutions so preservative in health and curative in disease as those we advocate; but it must be recollected that those institutions could contain their thousands of bathers at the same time, each bath being separate from the other, and that it was the practice of all ranks to bathe daily. Thus the baths of Dioclesius in Rome are said to have accommodated three thousand bathers, with a degree of luxury which to modern ideas would appear gorgeous in the extreme. After the dismemberment of the Roman Empire baths were again introduced into Europe from the East, where they still hold a rank second only in importance to the mosques.

Public Indifference. Is it that the beneficial experience of ages in so many civilised climes is not regarded? Or have the speculative and genius of our learned men and medical authorities been directed to more abstruse and therefore important objects of practical knowledge? The answer, if I feared, will be found in the indifference, nay, often absolute opposition, with which the British public too commonly meets individual efforts for its benefit. So accustomed are we to regard every new measure as a mere excuse for personal aggrandizement, that we commonly denounce the author and repudiate his recommendation. The Press nowadays holds in its hands the great power of making or breaking anything. But I will say it is now more disposed to favour any good cause than it used to be, and is more independent in its writings.

In no single instance has this statement been more conclusively verified than in London, so little attention being paid to appeals for means for the purpose made by men who are endeavouring to put before the public these great advantages, because they are a small body and I support special institutions.

A Great Safeguard. We are living in a time when the race for life is sharp, and sedentary occupations or over-indulgence in artificial habits of life predispose us for active physical exertion. It may, therefore, be taken for granted that appropriate bathing is one of the greatest safeguards against disease, especially of a zymotic character. The question suggests itself, cannot we re-acquire the immunity we are told the ancients enjoyed in this respect? We certainly have better houses; more attention is being paid to ventilation, drainage, and other sanitary improvements; according to the life statistics of the present day, actually four years is added to adult life, due, it is considered, entirely to our improved sanitary knowledge; and there can be no doubt that one great factor in personal health is "the frequent and thorough cleansing of the whole surface of our bodies," using plenty of water and a sufficient application of a fine emollient soap, like Pears', which soothes and softens the skin, besides being thoroughly cleansing.

I have endeavoured to show you that the principle of thermal and medicinal baths was fully understood by all the great nations of the world, and to these they were no doubt indebted largely for the excellence of their public health, which ceased as soon as bathing, through various causes, fell into disuse. There are obvious historical facts, which all who have any ideas of self-preservation, and have at heart their own and the public health, will do well to bear in mind. The microscopical and pathological science of the present day has taught us much about disease that was hidden from our forefathers.

The Romans, who were renowned for their luxurious and beautiful baths, prided themselves greatly on their

skins, especially the women. Why should not we do so?

Baths and the Skin. Baths act on and through the skin, and I will briefly touch upon the action of the bath upon the skin generally before I show you the special value of the various kinds of bath. The structure and functions of the skin have now been minutely and accurately explained to us by means of the microscope and scientific men, and from them we learn that the skin is composed of several parts: the outer or scarf-skin, which is being constantly cast off from our bodies in minute scales; but these, instead of falling away from our bodies, are retained on the surface by the clothing and become mingled with the perspiration, which unites together, forming a thin crust, attracting all sorts of particles of dust and foreign matter from the air, so that the whole body in the course of the day is covered with these particles, the consequence of which is, the pores of the skin become blocked up and its respiratory action prevented. In the second place, the skin must become irritated and damp and cold from the attraction of saline particles; as if any poisonous gases or infectious vapours find their way into the skin, they will find a suitable medium for transmission.

If, therefore, the pores be choked up, the elements of the transpired fluids will be thrown upon the system, and consequently removed by other organs than the skin, i.e., by the lungs, kidneys, and liver. Thus it must be obvious to us all that habits of uncleanness become the cause of consumption and other serious disorders of vital parts, and cutaneous eruptions and diseases of all kinds may be contracted.

With such grave considerations as these before us, bathing and washing become a necessity, and need no further argument.

Soap and Water. With regard to the water we bathe in, it necessarily holds a place which is spoken of as hard and soft. The softest water is distilled water, then river water, and lastly spring water. Hard water may be known by its property of curdling soap, but it may be rendered soft by adding to it a little potash or bicarbonate of soda. *The softer the water, the better it is for the skin.* Water has a natural repulsion for the oily matters given off by the skin. Soap, therefore, is necessary for their removal, and renders them easily soluble in water, hence it is an invaluable agent for purifying the skin. It is indispensable, indeed, for no other substance is so effectual. The purest and best oils are safe, and the soap already mentioned—that of Pears—is indisputably of flawless purity, as I have had occasion to professionally certify.

Soap and the Face. There is no reason why a little soap should not be applied to the face, although there is a very common impression among the profession as well as the laity that it should not be used there—that is, while soap is acknowledged to be useful and necessary to the skin of every other part of the body, on the face alone, which respects the rest of the surface in construction, the popular belief is that it should never be allowed. This is probably due to the possible annoyance caused by the soap getting into the eyes unless care be used. In direct opposition to this idea may be placed the fact that, in the treatment advised by most dermatologists where the sebaceous glands are disordered, as in seborrhoea and acne, great reliance is placed upon solutions of what is known as *sapo viridis*, a potash soft soap imported from Germany, whence this treatment originated, or even in the rubbing in of this soap itself.

Differences in Soaps. There are very great differences in soaps, and in their effects upon the skin, and as familiar extremes may be mentioned, on the one hand, the common yellow bar, or washing soap, and coarse soft soap, which are stimulating and very irritating to many skins, and, on the other, some of the best class of toilet soaps have little, if any, effect on the healthy skin except that of cleansing.

Requisites of a Good Soap. The requisites of good soaps are: First, that they shall not contain too much alkali, nor too little, just enough to saponify the fat, neither more nor less; secondly, that the fat from which they are made shall be good, pure, and sweet. For in the refuse sometimes employed for soap making

we may find decomposed matter; and cases are on record where pus globules were actually found in a soap which had caused and kept up a skin disease, and in another instance minute spicula of bone were found microscopically in soap which had produced an eruption on the face each time it was used for shaving. Thirdly, good soap must be perfectly mixed or, by preference, *boiled*, in order to produce the chemical process called saponification. The latter may be produced, to a certain degree, by cold mixture aided by pressure, but to make the best soap long-continued boiling is necessary. Fourthly, a good soap should be free from extraneous substances as largely as possible. Many of the cheaper soaps have clays and earths mixed with them to increase the bulk and reduce the cost; many are coloured, green, blue, red, etc., often with materials of very questionable value, and are scented with some of the strong perfumes, and of irritating character.

For all these reasons a good soap cannot be cheap, and great caution should be used to avoid those which are thrust upon the market, either as being very cheap or which are wrapped up showily, as these are pretty certain disguises for poor material. But a good soap, though it may cost more than common soaps, is the most economical.

"Medicated Soaps." A word may be added in reference to the so-called "medicated soaps" whose number and variety are legion, each claiming virtue far exceeding all others previously produced. The recounting of the varieties and vaunted virtues of these soaps would soon tire. Now all or most of this attempt to "medicate" soap is a *perfect farce*, a *delusion*, and a *snare to entrap the unwary and uneducated*. The healthy skin cannot be improved beyond health, and the diseased skin cannot be restored to health by any possible combination used in the form of soap that is employed by the laity.

"Soothing Soaps." Another class of soap, largely advertised and freely used, is what might be styled "the soothing soaps." As examples of these fancy soaps we have glycerine, honey, mallow, oatmeal, lettuce, and almond soaps, together with a host of others. Now these again are liable to adulteration, being too often made by unknown and irresponsible parties. At their best they can only be called harmless (but indeed they often are not that), and are in no way superior to a perfectly pure, carefully prepared soap without these supposed healing additions. In other words, soap is not and cannot be made healing, and where a healing application is required, it certainly should not and cannot be in the way of soap.

The Safest Soaps. The safest soaps to use are of course those that are the purest, the more expensive soaps of our best known manufacturers may generally be relied upon. There is, however, as I have said, *one soap* which stands quite above all question. This soap is Pears' Soap, which has first of all the recommendation from writers that it should be mentioned here, as *I can endorse all that has been written and said of it by the late Mr. Sturtin, Sir Erasmus Wilson, and Dr. Tilbury Fox*. It was through their instrumentality that, on account of its purity, Pears' soap was introduced into hospitals. It has obtained a world-wide reputation, and deservedly so.

In regard to the actual use of soap to the healthy skin, not a doubt can exist as to its value, for the greasy secretion and epidermal debris of the skin can only be removed by this means together with good friction. But, on the other hand, too frequent use of soap can, and frequently does, together with the water employed, cause actual disease of the skin. As an example of this we have what is known as the "washerwoman's itch," a distressing form of eczema of the hands, which is well-nigh incurable as long as the washing is persisted in.

As to the use of soap on the diseased skin, there is in general far more chance of doing harm with it than there is of doing good; for, while cleanliness is valuable or essential for health, too much washing can do much harm to many, if not most, skin diseases.

Eczema. The most common example of error in this regard is in the eczema of children—milk-crust or

tooth-rash, as it is sometimes called—where the mother will wash and wash the eruption in vain, using that and that soap in the hope of healing that which cannot heal, while a denuded and raw surface is continually deprived of the covering which is formed for the protection of the soft tissues beneath. The same is constantly done with certain ulcerative affections, as varicose ulcers, where cicatrization is impossible if the newly-growing, delicate, epidermal formations at the edges are removed by soap and water. These are but instances which might be multiplied, so that it may safely be said that the introduction of so many soaps has produced infinitely more harm than good.

Frequency of Ablution. In eczema of the scalp, both of adults and infants, I have seen the disease prolonged and spread, time and time again, by the unwise eagerness to wash. In these I allow the parts to be washed only by rule, that is, each time by special direction; perhaps in some cases it may not be permitted more than once a week, and then the part is to be rapidly dried, and the ointment or other dressing to be instantly applied. This is to form an artificial protection before the surface has had time to make its own protection in the way of an exudation from the surface. In this, as in most other rules of health, extremes should be avoided. As regards the frequency of ablution, the face and neck, from their necessary exposure to the atmosphere and the impurities which the latter contains, cannot escape with less than two washings in twenty-four hours; the feet, from the confined nature of the coverings, require at least one; the arm-pits, from their peculiar formation and secretions, one; the hands and arms as many as refined taste may dictate.

How to Wash the Face. Now let me advise you how to wash the face—few do it properly. *Fill the basin two-thirds full of fresh water; dip the face over it. It is in this stage that there may be danger, for there is no washing-glove like the hands; dip the face a second time, and thoroughly rinse it.* A little lemon-juice adds very greatly to the effect of this washing upon the skin of the face when added to the rinsing water.

Drying the Face. To dry the face a moderately soft towel could be used; a very rough towel is not desirable, nor a very thin one. A coarse towel will often produce excoriation on a tender skin. Such, then, is washing as intended for the purpose of cleanliness, but nothing is more refreshing than a thorough ablution, for as Thomson, in his poem on the "Seasons," has it—

"Even from the body's purity the mind
Receives a secret sympathetic aid."

The Wetted Sponge. The wetted sponge is one of the simplest and best methods of applying water to the skin of the weakly and delicate, and one by which the smallest extent of surface is exposed. The whole body in this way is quickly subjected to the influence of water, and to the useful process of consequent friction. A person of weakly constitution should commence a system of daily ablution in spring or summer, and by the winter he will be able to endure cold water without inconvenience; but this even should never be done without the doctor's sanction.

The Sponge Bath. The second form of ablution is by means of the sponge bath; the same precautions should be taken with this bath as the preceding as to the temperature and the constitution of the patient. Those who wish to pass the short time of life in good health ought often to use cold bathing. I can scarcely explain to you how much benefit may be had by taking cold baths with care. For they who use them (although perhaps growing old) have a strong pulse and a high complexion, are active and strong, their appetite and digestion are good, and all their natural actions are well performed. As Sir John Foy says, "They reach the very soul of the animal, rendering it more brisk and lively in all its operations."

The Shower Bath. Of the shower bath I shall not say much; it is only suitable for very vigorous constitutions, and should be advised by medical men with the greatest care.

Swimming Bath. The swimming bath, both in salt and fresh water, taken at suitable times of the year, is one of the most healthy and invigorating of all kinds of bathing, especially to the young. *Let me advise you, fathers and mothers, have all your children, girls as well as boys, taught to swim.*

There is one popular error about swimming in salt or fresh water—the young are apt to stay in the water too long. I have seen serious results occur from this.

The Warm Bath. When the cold bath is disagreeable to the sensations of the skin of the bather, it may be raised in temperature to taste, viz., to 75 or 85 degrees, to suit his feelings. It then alters its character—to the temperate, 75 to 85 degrees; tepid, from 85 to 95 degrees; warm, 95 to 98 degrees; hot, 98 to 105 degrees. To those who have passed the middle part of life, have dry skins, and begin to emaciate, says Darwin, "The warm bath, for half-an-hour, twice a week, I believe to be eminently serviceable in retarding the advances of age."

The Turkish Bath. The vapour bath, or Turkish bath, so valuable in many disorders of the skin, is next in order of precedence. The bather seats himself in a chair, or sits in a hot room, and the vapour is turned on gradually from 90 to 110 degrees. The vapour is breathed, and is thus brought in contact with every part of the lungs. The first sensation is one of irritation, with some slight difficulty of breathing; but soon the perspiration bursts through the pores and all becomes agreeable; the perspiration rushes out on to the skin. From this the bather goes into a tepid bath, remaining there for ten minutes. He then quits the bath and dries himself with warm towels. Sometimes cold effusion is added to this by the advice of the medical attendant.

With reference to cold bathing, Sir George le Fevre makes the following judicious caution: "*Do not wait until the body becomes cold before you plunge into the water.* It is in this stage that there may be danger, for the external excitement has passed away, and the body cannot resist the depressing influence of cold."

Effects of Bathing. Now, with regard to the physiological effects of bathing. When the body is moistened with the sponge or wetted with cold water, the skin immediately shrinks and all its tissues contract; as a result of this contraction the blood is thrown back on the internal organs and nervous system, which are stimulated by this flow of blood, causing a more energetic action of the heart and the blood-vessels of the skin. *This reaction is the prime object of all forms of bathing, and upon it depends the healthy action of the skin.* In order to increase this reaction various methods and manipulations are resorted to.

Shampooing. The operation of shampooing is a good one; as in the Turkish bath, many an imaginary ailment and stiffness of body or limb, many an eruption of the skin is caused to vanish by this means, when aided by skilful treatment. Indeed, in my experience, many so-called incurable eruptions will yield if treated rationally and carefully.

Baths, in the ordinary acceptation of the word, are the immersion of the body in a medium different from air, which medium is usually common water.

Soap Substitutes. Bathing has served both for cleanliness and pleasure, and has been practised by almost every nation.

The richer Romans used every variety of oils and pomades (smegmata); they scarcely had soap in those days. They used flowers of lentils, as used at the present time by Orientals. The most important instrument used was the astragalus, a curved instrument of metal, and used as a scraper.

Action of Baths on the System. That is, the action of heat and cold on the cutaneous surface through the medium of water.

It is generally supposed that water acts on the system by being absorbed by the skin. This question has been frequently discussed, but the great majority of observers believe that under ordinary circumstances little or no water or medicinal substance is absorbed into the system—it is merely a stimulant action imparted to the skin.

The powerful influence of water on the capillaries of the skin, and the mode and extent of that operation,

depend upon the temperature of the fluid in which it is immersed.

Baths have, therefore, to be considered according to their temperature. The cutaneous surface bears changes of temperature far much better than changes of temperature of water. For instance, air at 75 degrees, is perhaps too warm for the feeling of many, but a continued bath at that temperature is cold and depressing in like manner, a bath of 68 to 102 degrees acts as a stimulant, as, being a good conductor of heat, it suffices the perspiration. A temperature a few degrees below blood heat can be borne longest without any disturbance to the system.

Cold Baths. Cold baths act by refrigeration, and their effects vary according to the degree of temperature.

The effects of a cold bath at about 50 degrees are diminution of the temperature of the skin and of the subjacent tissues; the blood rises in temperature to nearly four degrees, soon subsiding, that is after the bath has been taken.

At first the surface becomes pale, and its capillaries contract. Then there takes place a reaction, bringing redness to the surface and increase of temperature. Very cold baths, i.e., below 50 degrees, cannot be borne long.

We should not lower the temperature of the skin below 9 degrees, as a further reduction may prove fatal.

Effects of Hydropathy. The effects of hydropathy depend upon the power of abstracting heat from the body, and of stimulating it by the application of cold water. Under the process of hydropathy the system is subjected to periods of excitement and rest. That is, persistent lowering of the temperature of the body, with capillary contraction and anæmia. This is succeeded by a period of reverse or local hyperæmia, accompanied by excitement of the vascular and nervous systems, and the processes of absorption and excretion are stimulated, with increase of perspiration. We now consider the effect of warm bathing at different temperatures.

Temid Baths. Tepid, 85 to 95 degrees. The bath at this temperature is only confined to the surface, or the peripheral extremities of the nerves, and does not extend to the central system, and consequently can be borne an indefinite time.

Warm Baths. Warm baths, from 95 to 100 degrees. In these the heat is propagated to the surface to the central system, causing reaction and increased surface circulation, giving slight stimulus for the renewal of tissue.

The Hot Bath. Hot bath, from 102 to 110 degrees. Here the central circulation and nervous system are more affected. The skin is congested, and the retained heat bursts out in perspiration.

A very hot bath, about 110 to 115 degrees, almost scalding, cannot be borne many minutes, causing violent reflex reaction on the heart and circulatory system.

Vapour baths produce profuse perspiration and action, cleansing the skin. They do not act so rapidly on the skin as the warm bath, and consequently can be borne longer and hotter; but a higher heat than 122 degrees cannot be borne comfortably.

Hot air baths differ from vapour baths in not impeding the perspiration, and these baths again induce more perspiration than the vapour baths.

Vapour Baths. Vapour baths, hot air, and many hydropathic processes agree in producing violent perspiration. Of perspiration: It is sensible and insensible; three ounces may be considered to be about the average thrown off in twenty-four hours, consisting chiefly of water; about one-third consists of urea and other excretory products.

In comparing the general effects of hot and cold bathing, it may be said, while the former tends to check the perspiration the latter favours it. It is said that cold baths, by the reaction they promote, increase the action of the gastric and other fluids of the stomach and alimentary canal, and warm baths rather serve to retard it.

As regards the use of baths simply for the promotion of health, it follows from what I have said that warm

baths are best suited for the delicate, the very young, and the old, cold baths for the strong and robust, when the powers of reaction are unimpaired.

Warm baths, according to their degree of heat, are useful in calming the nervous system, in neuralgia, in rheumatism, and gout.

Turkish baths are useful in the latter affection, and whenever it is desirable there should be more free action of the skin.

Cold baths, again, are useful when the skin and system require tonics, and it can bear the shock of cold affusion.

Injudicious Bathing. Long-continued warm baths are soporific, and have often by this action caused drowning.

The effects of too hot baths are swimming of the head, vomiting, fainting, congestion of the brain, and apoplexy.

It is, therefore, very evident that much caution should be used by people of weak hearts in not taking their baths too hot. Fat men and those disposed to epilepsy should not take them too hot.

Bleeding Risks. The risk in cold bathing is congestion of the internal organs, as often indicated by the lips and fingers turning blue; extremely cold baths should therefore be interdicted when there is a tendency to internal congestion, and they are always dangerous when the system is exhausted by fatigue.

The warm bath causes swelling and congestion of the capillaries of the surface in the first instance; when the stimulus is withdrawn the contraction takes place. A cold bath, again, first causes contraction of the capillaries of the surface, which is followed by their expansion when reaction sets in.

The reason why a man feels refreshed by a hot bath when exhausted, may be that the increased heat conveyed to him by the warm bath, helps the process of oxidation, and thus relieves the system.

Cold refreshes by exciting the functions, heat by necessarily relieving their action. The general result of these comparisons would show that warm are a milder remedy than cold baths, and are applicable often when the system does not possess power of reaction sufficient to make use of the latter expedient.

Now as to a few words of advice.

Time for Bathing. Whenever it is possible bathing should be over before 10 o'clock p.m., never bath when the stomach is loaded with food, or after much stimulants. The shorter the bath is, especially when cold and the bather cannot swim, the better—say five minutes. If he can swim, fifteen or twenty minutes is quite enough.

Bathing should not be practised more than once a day; when the body is very hot, not exhausted, it is advisable to bathe at once, not to cool. Care should be taken after vapour or hot-air baths not to get cold.

Baths for Skin Eruptions. The baths we usually prescribe in certain eruptions of the skin are the vapour and the simple medicated warm bath, which can be made to resemble in character most of the natural mineral waters. These baths admit not only of having the temperature raised or depressed at pleasure, but can be medicated with various drugs according to the nature and requirements of the case. They are used chiefly for the purpose of bringing about a healthy action of the skin, relieving irritable conditions, and allowing the more thorough application of drugs.

The simple vapour bath is a very valuable adjunct in many eruptions of the skin. The bather seats himself in a box (the cabinet Turkish bath) on a chair, or on a cane-bottomed chair surrounded by a blanket, with a spirit or gas condenser under the seat. The temperature can be raised or lowered at will from 50 to 120 degrees.

The Turkish bath is much the same in its process of action. The bather may remain in the bath twenty minutes to half an hour.

Take Care of Your Skin. Having now recounted to you all the various methods of diet, clothing, and bathing, which I know to be the best to promote a good complexion, it is your duty, I venture to say, to take care of your skin as you value the treasure of a good complexion and a healthy skin.

The Romance of the House of Pears

By CLEMENT K. SHORTER

(Reprinted with additions from THE SPHERE, by Special Permission of the Proprietors.)

The story of the Pears' business goes back to the year 1789, when one Andrew Pears, the founder of the house, invented the soap which has long been of world-wide fame. He was the son of a farmer on the Lander Farm, near Melbury in Dorset, and coming up to London set up a small barber's shop in Gerrard Street, Soho, where the customary barber's pole indicated his profession. In addition to operating upon such customers as called upon him, he used to have his regular round of daily visits among ladies and gentlemen who wanted their wigs powdered or required other toilet attentions which came within his province.

He knew—no one better—how defective the toilet soaps of his day and generation were, and it was to remedy this defect that he bent his abilities to the producing of a soap that would enable him to perform his duties with greater comfort to his customers and more credit and convenience to himself. This was the *raison d'être* of Pears' Soap. And presently he discovered that he had "blundered better than he knew." The soap which served his own needs so well was equally efficacious with equal efficiency to the needs of whomsoever could be got to buy it.

But good old Andrew Pears, clever inventor as he was and proficient as he was in his calling, did not understand much about the science of selling. Indeed, the art of creating demand by advertising was hardly thought of at that time. Here and there, now and then, Mr. Pears was obliged to put out a modest announcement, informing the public of the merits of his new "transparent" soap, but these advertisements did not rise much above the level of the ordinary perfumery's trade circular. Still, the soap was a good, pure, honest toilet soap, far exceeding in true saponaceous merit the other soaps then on the market; and those who used it acknowledged this and commended the article; but this was hardly sufficient for the building up of a great prosperity.

Andrew Pears was shrewd, however, in his old-fashioned way, and watchful of his interests, and when he found that unscrupulous dealers were imitating—not the soap itself, for that was beyond them—but the wrappings, colour, and method of presentation, he thought he would upset their "knavish tricks" by simply signing each package with his own signature, actually written by himself with his own business quill. To imitate that would have been forgery, for which there was remedy enough, although there might be no redress in those days for the other offence. And so matters went on placidly and evenly, without the Thames or any other stream being set on fire by any Pears' pronouncement of awakening importance.

In 1835, Andrew Pears, who then for some years had been established in a shop, now pulled down, at 55, Wells St., Oxford St., and by this time was getting into years, decided upon taking his grandson, Mr. Francis Pears, into the business.

Transitions. And from that time onward the style of the firm has been "A. & F. Pears."

Andrew and Francis Pears continued together until 1868; then for several years more Francis Pears carried on the enterprise alone, keeping the business alive in a small way with an expenditure of some £80 per annum, until at last it had either to be brought into line with altered business conditions or drop out

of the running. The soap was there still, as good and as worthy of public patronage as ever, but that was nearly all that could be said about it. It had yielded a modest, but in no sense large income to its proprietors, and as they had manifested little disposition to force a larger market it seemed as if the splendid idea of the original Andrew Pears would ultimately fade from public notice. It was saved from this fate, however, by the introduction of young new blood into the firm in 1865, in which year Mr. Thomas J. Barratt and Mr. Andrew Pears (son of Francis, and great-grandson of the original Andrew Pears) became joint proprietors with Mr. Francis Pears with a total capital of £7,000. Francis Pears proposed to make the name of the firm "Pears and Barratt," but for advertising and other reasons Mr. Barratt objected.

This was the starting of the new Pears' era, and resulted in the gradual adoption by Mr. Barratt of two new business forces: that of publicity or selling power, and that of increased facilities of production.

The New Pears' Era. While Mr. Andrew Pears assumed the superintendence of the factory at Isleworth, Mr. Barratt at the London headquarters became the controlling spirit of the undertaking, and it was due to his resourceful initiative, and strong will, that the old enterprise was galvanised into new life and forced into the current of the time. While Francis Pears remained in the concern, however, it was difficult for Mr. Barratt to free himself and the business from the old-time influences. Nothing could entirely divert the mind of Francis Pears from the business methods under which he had been brought up, and he often looked with distrust, and sometimes with dismay, upon the progressive and aggressive ideas with which Mr. Barratt sought to win wider popularity for the good old soap. New suggestions were from time to time acted upon, sometimes they were not, Mr. Pears' frankly confessing his inability to follow them, and not daring too much for fear that he should lose all. New ideas entailed new expenses, and although Mr. Barratt never took up with a project in which he had not confidence, he was often unable to inspire the same confidence in the respected senior partner. As matter of fact, times of financial stress occasionally ensued, but Mr. Barratt was no less successful in coping with difficulties of this nature than with the promulgation and putting into operation of the new advertising features with which he meant to conquer the markets of the world for Pears' Soap.

"You may be right, but I have my fears," Mr. Pears used to say, so, in the end, with the object of making sure of something for himself for his

Retirement of Francis Pears. old age, while yet there was any thing left to realise upon, he finally retired in 1875, leaving £4,000 of his own capital behind him in the business as a loan, to be discharged by Mr. Andrew Pears and Mr. Barratt equally. This was not a too promising start, it must be admitted. A quite small capital and a loan of £4,000, upon which interest had to be paid, did not leave much margin for expensive operations. But Mr. Barratt believed in the soap, and in his own capacity to sell it, and never allowed himself to lose heart; so by careful financing and the exercise of much energy and thought, the business was gradually put on its feet, and Francis Pears' loan was repaid. It was in those years of struggle that Mr. Barratt was able to show that he possessed the true business in-

instincts which not only enable a man to achieve success, but also inspires confidence in others. Often it was this confidence that others had in him that was the means of giving the firm over a difficult financial period, when the prospect and promise lay in the future; but Mr. Barratt was always able to show a clear outlook devoid of complications. He saw what the business was, capable of under his direction, and inspired others also to a great extent, which fact bridged over many a financial crisis, and in time the enterprise became successful, and thenceforward its history was one of rapid expansion.

It was the advertising question which had puzzled Francis Pears. Its cost seemed a thing beyond recouping. He did not think of it as "bread cast upon the waters," but as to a large extent, money thrown away.

The Advertising Question.

It was really a matter that was out of the range of his thinking. In economies pertaining to management and organisation, Mr. Barratt was at one with him; but when it came to spending money on a well-thought-out system of advertising, Mr. Pears could not see eye to eye with his young partner. The latter, however, had studied the advertising field with great care, and making his own calculations, drawing his own conclusions, devising his methods, and throwing his whole energies into the work, he soon succeeded in convincing the public of the one great truth that he had convinced himself upon at the outset, viz., that as there was no better soap made or makeable than that of Pears, it was a worthy and an honourable work to devote himself to making that truth known to the world; not omitting from the purview, of course, the prospect of, at the same time, and as a natural result, building up a great business for the House of Pears.

It was a small business indeed. The Great Barratt first came into it. The Great Russell Street place and then the works at Isleworth only worked one or three times a week, and very few hands were necessary to the working. Mr Pears resided in the house adjoining, which he called "Lanadron," after the Cornish farm on which the first Andrew Pears had lived, and in this primitive fashion the manufacture of Pears' Soap was carried on in the early days of the partnership.

The only office of Messrs. A. & T. Pears, when Mr. Barratt joined, was a little room behind the shop at 91, Great Russell Street, Bloomsbury, not far from the British Museum, and the staff was a retail shopwoman. Mr. Barratt not only kept the books but did the travelling. The first cash book used by what may be called the new firm is still among the ancient treasures of the house. The entries are all in Mr. Barratt's own handwriting. He kept it for years. In its pages may be noted such items as "Expenses to Hastings, Eastbourne and Tunbridge Wells, £11.5.0." for a journey to three towns in search of orders. Economy and Pears' Soap were even then ideas of intimate association. Meanwhile, the works at Isleworth, where the soap was made, were being gradually brought into line by Mr. Andrew Pears, with progressive methods of production, and nothing was wanting but an increased demand to win an assured success. Mr. Barratt decided that the key to the world's markets was advertising, and he resolved he would give a new polish and a new power to that key.

Everybody in these days is so familiar with large scale advertising that it is difficult to comprehend how the publicity problem stood up. There were no large advertisers in the present-day sense, at that time. The newspapers carried only a very small number of advertisements, and few of any size. The leading business houses rather "looked down" on advertisers and advertising, and the papers themselves did little to encourage extension of business in this direction, while poster advertising was insignificant in quantity and poor in quality, indeed, the caution "Bill Stickers will be Prosecuted," was one of the most prominent. In Mr. Barratt's view, it was just as

legitimate and honest and proper to appeal to the public by the medium of a well-worded advertisement as it was to send travellers out to seek orders. Both methods were on the same level. Wherever the field was promising, Mr. Barratt had the courage to venture, but it was no haphazard, blindfold leaping in the dark with him. He studied the advertising outlook with a seriousness and a pertinacity that yielded much knowledge, summed if not a little strange and peculiar, and bringing him many curious experiences.

Advertising, however, was a rather expensive affair even forty-five years ago, and well-established as the Pears' little enterprise then was,

Strong Contrasts.

in its old-fashioned way, its capital was not large enough to admit of lavish expenditure—least of all any experiments—on publicity. Still, by dint of much thinking and some ingenuity, and backed by a strong determination, Pears' Soap managed to get into the full advertising "swim." What this meant cannot be better summarised than by this one simple statement: when Mr. Barratt joined the Pears' business it was quite a retail one on which perhaps in the eighty years or so of its existence not more than £500 all told had been spent in advertising; while not so very many years later, when the new advertising ideas were in full swing, Mr. Barratt spent as much as £250,000 in a single year on advertising in its various forms—each season bringing forth a bountiful crop of new Pears' press advertisements, new Pears' posters, new Pears' railway advertisements, and new everything. And so the old business, in alert and progressive hands, prospered; and in due time the modest building in Great Russell Street had to be "retired" or "superannuated"—for it is still sentimentally retained as part of the Pears' enterprise—and the marble palace and art gallery now forming the Pears' new quarters, in New Oxford Street came to be established, to which, however, it had been at 38, Great Russell Street, opposite the old shop there, whilst acres of factory buildings had been erected at Isleworth.

It was not until Mr. Barratt took the matter up and made his investigations that the true importance of Pears' Soap came to be known

The Newer Cult of Beauty.

to the public. When he told the story of its invention and demonstrated by expert and other evidence what were the great qualities of the soap, people who had never heard of it before were made to buy and use it, and once used its worth was made sufficiently manifest. Mr. Barratt proved to the world that after the introduction of Pears' soap, the cult of beauty entered upon a new phase. Up to that time, he clearly showed, toilet soaps had been of such inferior quality, and made of such crude materials, it was not to be wondered at perhaps that women should have resorted to charlatans, who professed to be able to make them beautiful with pastes, potions, washes, ointments, and what not. Nature had been woefully misunderstood. Pears' Soap helped to restore Nature to her rightful place in the hygiene of the skin. Every component of Pears' was absolutely pure, while in its combination it represented such an exquisite balance and harmony of saponaceous ingredients as had never before been realised. The skin responded to its every touch. It brought to bear a new emollient influence that worked for beauty all the time, and set up a natural action that induced and preserved natural beauty of complexion—the natural pink and white of perfect loveliness.

Then with the dawn of what may be called the era of natural beauty, an improved comprehension of the true conditions of beauty ensued. At first the movement was confined to a few ladies of the Court and Society, but when it became matter of common knowledge that good looks could be better preserved by Pears' than by cosmetics and other artificial preparations, the example was widely followed. Pears' thus became distinctly associated with the cult of beauty, and the most celebrated beauties of six generations have borne enthusiastic testimony to the fact that Pears' has been of unsurpassable service to them in the improving and maintaining of their perfect complexions.

Pears' Soap has held the leading position among

Grellfenghagen, R.I., Gordon Brown, R.I., R. Caton Wood, and many others. This production has won its way into popularity precisely in the same manner as Pears' Soap has done, by sheer force of merit. Some 300 tons of paper is consumed in a single issue of the *Annual*, and 150 pair-horse vans are required to deliver it. Another side of Pears' literary production is represented by *Pears' Cyclopaedia*, of which this volume is a copy of the latest edition, which brings the total issue up to 1,200,000 copies. It consists of 1,070 pages and twenty separate sections, and is universally pronounced to be the most remarkable shillingworth of useful literature ever produced. It is a work which is serviceable to all classes of the community—a book of daily utility for the home or the office—and a great storehouse of practical knowledge. Two or three editions are issued every year, each one being brought up to the time of publishing in every section.

All along Mr. Barratt held to one or two cardinal principles of advertising faith—first, not to claim impossible qualities for the article advertised, but to claim all that can rightly be claimed; and to that extent to insist and insist and insist by the strongest forms of publicity that can be devised. One of the forms that he always favoured was the artistic form. He was greatly helped by certain artistic instincts and tastes, which not only prescribed something of an artistic standard for his advertising appeals, but invariably induced him to employ more or less artistic line.

Mr. Barratt's Advertising Faith.

Lord Northcliffe in a public speech once paid Mr. Barratt the compliment of styling him "The Father of Modern Advertising from whom I have learned so much." Pears' Soap is bought by the public at immensely lower prices now than nearly £3,000,000 has been spent on advertising than when less than £500 was spent in advertisement.

In Mr. Barratt's early advertising days, art had hardly been thought of in connection with publicity. The pictorial poster of true artistic effect, and the illustrated advertisement which was to be drawn and produced by the best artistic talent, had not arrived. It is now the dominant note in the best advertising.

"I have heard it urged," said Mr. Barratt, one day to a *Daily Mail* interviewer "that an article that is largely advertised must be costly. Well, those who affirm these things know nothing about it, and certainly cannot have given the subject any serious thought, for the reverse is entirely the case. Their argument could only hold good if advertising produced no extra demand for an advertised article: and who would advertise at all if that were the case? It is one of the leading factors—the leading factor of all—in the economics of advertising, that successful advertising means such an increase of sale as not only enables production to be cheapened at every point but enables the quality of the article to be improved, if possible. This is entirely to the advantage of the consumer, and its advantage to the advertiser is that, although the profit on each single article taken by itself may be diminished, in the aggregation of things, and considered by the bulk, there is still an adequate profit left after advertising and all other expenses have been satisfied. The balance is on the right side both with producer and consumer, and at the same time, by the money which has been put into circulation through the Press and other channels, many industries have been benefited, and the sources of employment have been multiplied and augmented."

Good advertising cheapens Cost.

Costly. Well, those who affirm these things know nothing about it, and certainly cannot have given the subject any serious thought, for the reverse is entirely the case. Their argument could only hold good if advertising produced no extra demand for an advertised article: and who would advertise at all if that were the case? It is one of the leading factors—the leading factor of all—in the economics of advertising, that successful advertising means such an increase of sale as not only enables production to be cheapened at every point but enables the quality of the article to be improved, if possible. This is entirely to the advantage of the consumer, and its advantage to the advertiser is that, although the profit on each single article taken by itself may be diminished, in the aggregation of things, and considered by the bulk, there is still an adequate profit left after advertising and all other expenses have been satisfied. The balance is on the right side both with producer and consumer, and at the same time, by the money which has been put into circulation through the Press and other channels, many industries have been benefited, and the sources of employment have been multiplied and augmented."

Poets and Parliament. Sir Theodore Gordon Barratt discovered the secret of Helen's beauty in a golden casket; how he

"Eagerly the lid uncloses,

And lo! it is laid aslope,

Fragrant of the sweet roses.

Cake of Pears' Transparent Soap."

Among the parliamentary references to Pears' Soap, Mr. Gladstone's metaphorical allusion on a certain occasion when he wished to convey the impression of vast numbers. "They are as numerous," he said, "as the advertisements of Pears' Soap, or as autumn leaves in Vallombrosa." This, by the way, was the first debate in which Mr. Lloyd George took part.

A Pears' advertising idea once led to the passing of an Act of Parliament. In the early 'eighties French ten-centime pieces were in considerable circulation in this country and were accepted as the equivalent of English pence. Mr. Barratt saw an advertising opportunity in this, and imported 50,000 of the coins, had them all stamped with the word "Pears," and put them into circulation by the aid of commissionaires. It was a splendid run that was obtained for the money—while it lasted—but the Pears' pennies became so persistently numerous that at last a special Act of Parliament was passed making French coin illegal after a certain date. The Government bought up all the Pears' pennies and melted them down. Meanwhile Messrs. Pears had had their advertisement.

No wonder that with this brilliant and persistent advertising, the demand for Pears' Soap should have increased at such an amazing rate as to make it necessary greatly to enlarge the Isleworth factories, where Mr. Andrew Pears, always loyal to Mr. Barratt's forward policy, continued to direct affairs, and where Mr. Andrew Pears died in 1900. It was a satisfaction to know that there had never been a word of misunderstanding of any kind between the two.

Mr. Barratt was a firm believer in to-day, but a still firmer believer in to-morrow. The Pears' policy is always a forward policy. In advertising—that is, successful advertising—one business is with the future. Tastes change, fashions change, and the advertiser has to change with them. An idea that was effective a generation ago would fail if presented to the public to-day. Not that the idea of to-day is always better than the older idea, but it is different—it hits the present taste. Mr. Pears have had many what may be called extra successes—especially in pictorial and art advertising—generally they have been so good as to seem almost of perennial attractiveness. See John Millais's "Bubble" painting, for instance, for which £2,200 was paid, and certain other works, not unknown to fame and the map in the street, by Stacy Marks, Phil May and others—all these things were of special mark and of lasting influence. But when they are repeated, it is in some new form. At one time they are going their way through the Press, at another time contributing to the attractions of the National Gallery, the Street Hoardings, and at another flooding the magazines and periodicals in inset form. But in all these ways it is "to-morrow, and to-morrow, and to-morrow" that Pears have to be continually striving for in advance, and so it was, and so it may be supposed "to the last syllable of recorded time." And the good, honest soap that Andrew Pears invented in 1789 is now enjoying a world-wide popularity, thanks to a strong business policy that since 1865 has utilised advertising as a means of making the supreme quality of the article known over all the ends of the earth. It is this business policy, inaugurated forty-five years ago, which has made the name of Pears universal. Pears' business was then a small one with a £2,000 and a product little known; under the new system of operations have been multiplied a hundred-fold, and to-day it has a market value of over a million and fifty thousand pounds. Mr. Barratt brought the name of Pears out of obscurity, planted it in full view of the universe, and practically made it sell soap.
